THE following case of typhoid fever appears worthy of recording having an incubation period of at least 141 days. The patient was a convict and during the whole of this period was in H.M 's prisons under medical supervision, and although the incubation period may have been longer than that stated it can be proved to be of at least that duration. The events preceding the convict s reception to this prison, which are of importance, are as follows. Sentenced by military court-martial in South Africa to a term of penal servitude, he was sent to Pretoria a prisoner and then to Cape Town, where he arrived about March 2nd, 1902 Seven days later he embarked for Southampton, arriving on April 1st He then passed a few days in a military prison and was received at H.M 's prison, Lewes, on April 21st The medical papers of the patient to which I have access are those which accompanied him in the civil prisons and date from his reception into Lewes prison, the dates previous to this are only approximate, being furnished by the patient's memory On his reception into Lewes prison he stated that he had not suffered from any special illness and that during the whole period of his detention there he was in perfect health On August 25th he was transferred to H.M.'s convict prison Portland, likewise in perfect health, well developed, and muscular, his height was six feet and half an inch and his weight was 182 pounds. He was set to work in the blacksmiths' shop On Sept. 1st he was admitted to hospital, the outer side of the left foot and ankle were inflamed, having been chafed by an ill fitting boot. He was discharged well on the 8th Four days later, on the afternoon of Sept. 12th, he was readmitted to hospital, complaining of headache and shivering On examination his pulse was rapid and his temperature was 102° F rising in the evening to 104°, he had headache and slight bronchial catarrh, evidenced by occasional rhonchus, the abdomen appeared to be normal, the spleen was not palpable and there was no roseola, he had no diarrhœa. The tongue was slightly furred. He informed me that the day after he left hospital—that is, Sept. 9th—he had not felt well and had gradually been getting worse. On the 17th three rose spots were found on the trunk. Typhoid fever was definitely diagnosed and this opinion was confirmed by the Widal reaction On the 19th the laboratory report of the Clinical Research Association was received, to the effect that tests made from the patient's serum with dilutions of 1 in 10, 1 in 25, and 1 in 50 gave positive reactions. The patient is now well, having passed through a moderately severe attack of typhoid fever with relapse, he had occasional retention of urine and at one time signs of cardiac failure caused anxiety, "tender toes," with signs of a local neuritis, lasted for a few days, but the cold bath treatment had not been used.

As soon as the diagnosis was made it befell one to endeavour to trace the origin of the attack. Dr W A. Dow, medical officer of Lewes prison, reported that there was no typhoid fever in that prison and further kindly reported (Dec 19th) that the medical officer of health of Lewes had had no case notified since March 20th At Portland prison there had been no typhoid fever for some years and Dr D J Lawson, medical officer of health of Portland, kindly reported that no case had been notified to him for six months before our patient was attacked It has been an isolated case and so could not have been due to diet, all of which, except water, milk, and cheese, is cooked before being served. Had it been so with a convict population of over 700 some other case would certainly have occurred. The result of a bacteriological examination of the milk- and water supply carried out at the Government laboratories was negative It was therefore impossible for infection to have taken place at either this or Lewes prison It transpired that on the journey from the latter to this prison, the prisoners being transferred, the patient and three other convicts were given a glass of water to drink at Weymouth station Could this have caused the infection? The three other convicts have remained in perfect health and Dr T H. Jones, medical officer of health of Weymouth, kindly informed me that no case of typhoid fever was notified to him in July, August, or September The patient could not, therefore, have been infected by this glass of water It is obvious that infection took place at some date previous to reception into Lewes prison The patient himself considers that infection took place at Pretoria, but of course this is only a supposition, there was little illness on the ship in which he came to England and his kit was used only by himself. This case is reported with the permission of the Directors of Convict Prisons.

Portland Prison Hospital

CASES OF ASSOCIATED PNEUMONIA AND PSEUDO DIPHTHERIA

BY JOHN REID M.D ABERD

IT is well known that various cocci, more particularly streptococci, staphylococci, and pneumococci, are almost always found associated with the Klebs-Löffler bacilli in diphtheria and it is also recognised that several morbid conditions are attended with the formation of membrane or exudate more or less resembling that of diphtheria but entirely independent of the Klebs Löffler bacillus. The organisms present in the last-mentioned class of cases are streptococci, staphylococci, diplococci, and the bacilli of pseudo-diphtheria. These bacilli resemble the Klebs-Löffler bacilli to some extent but can be distinguished from

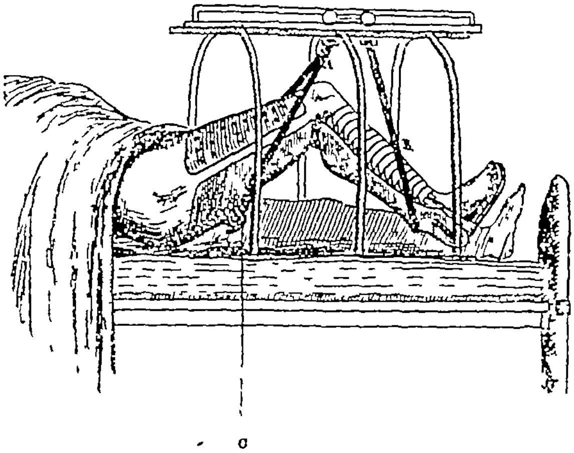
A NEW METHOD OF TREATING FRACTURES OF THE SHAFT OF THE FEMUR

BY J P LOCKHART MUMMERY, F R C S ENG,
DEMONSTRATOR OF OPERATIVE SURGERY AT ST GEORGE'S HOSPITAL.

FRACTURES of the shaft of the femur are among the most difficult to deal with satisfactorily that the surgeon is called upon to treat and the results of mal union are often very serious to the patient Any shortening in the thigh will of necessity bring the knee-joint on that side out of alignment with its fellow and so make a difference in the level of the two knee-joints. Thus patients with shortening above the knee walk more lamely than would be the case with a similar amount of shortening below it. There are several reasons which render these fractures particularly difficult to deal with. The bone in a well developed subject is covered by a thick layer of muscles and is a long way from the skin surface, it is, therefore, difficult to ascertain the exact position of the fractured ends with any degree of certainty and to manipulate them into position when found. The muscles pulling on the fragments are probably the most powerful in the body (the glutei, hamstrings, quadriceps, &c.) and tend to make the fractured ends override each other, besides necessitating the use of powerful extension to overcome their pull Also, the limb below the site of fracture is long and heavy, so that almost any movement of the patient's body is liable to result in movement taking place at the site of fracture in spite of the most carefully adjusted splints It is now a well recognised practice to endeavour to bring the bones into place by position rather than by force and to bring the distal fragment into line with the proximal one the joints being so bent as to relax as far as possible the muscles tending to displace the fragments. (This was particularly pointed out by Sir William Bennett in an article in the *Practitioner* for August, 1901)

More or less powerful extension, however, is almost always necessary in treating fractures of the femur, for it is not to be expected that weights of a few pounds will overcome the pull of such powerful muscles as those involved. The best way of obtaining efficient extension is undoubtedly by making the distal portion of the leg the fixed point and allowing the body weight to act as the extending force, powerful extension can in this way be secured by very simple apparatus. Probably the best splints at present in use which attain these objects are "the double incline plane" and "the Hodgen's splint", in both of these the weight of the upper part of the limb tending to slide off the splint acts as the extending force (The "double incline plane," to be efficient, should have the thigh piece at least two inches too long for the thigh) The Hodgen's splint is, however, somewhat tiresome to adjust and entails a good deal of rather complicated apparatus, while "the double incline plane" has the twofold objection that it is very troublesome to nurse patients with and there is no means of steadying the thigh laterally The following method, which is in a sense a modification of both, is, I venture to think, simpler and more easily managed than either, while at the same time remaining quite as efficient.

The splint is applied as follows An extension stirrup is applied with strapping from the ankle to the knee in the usual way and the stirrup is fixed round the foot-piece of a Macintyre's splint, the thigh piece of which should be made long enough to reach well up to the fold of the buttock. On the under side of the thigh piece and close to its upper margin a metal hook is fixed (see illustration) The best splint for the purpose is a Macintyre made so that the length of the thigh piece can be adjusted by means of a thumb-screw and with a flat metal hook attached to the under side. An anterior splint for the thigh is then made of Gooch's splinting, or, better, of gutta percha, padded with a double layer of lint, and fixed to the thigh with webbings passed round the Macintyre splint. The fracture having been set the splint is now adjusted with the knee bent nearly to a right angle and the limb is fixed with bandages or webbings, as the case may be A leather strap, which should be about an inch in breadth, is now passed through the lugs on the carriage of a Salter's cradle, then round the thigh piece of the splint and caught in the hook on the under side. The buckle is then brought to one side and the strap is tightened until the buttock and the thigh on that side are lifted off the bed, when the strap is sufficiently tight it ought to be possible to pass the open hand beneath the buttock on the injured side. Another strap is then passed round the lower end of the splint and fixed to the cradle to support the leg, this strap must not be too tight or it will depress the upper end of the splint. The upper strap will need tightening from time to time to make up for stretching, &c All that is necessary in order to examine the site of fracture is to remove the anterior thigh splint.



c Hook on splint round which strap A passes

By this method very powerful extension can be easily secured and with very little attention will remain efficient. The weight of the thigh and buttock tending to slide off the splint draws the upper fragment away from the lower, the latter is prevented from moving by the extension strapping and stirrup round the foot-piece and by the bent position of the limb

The chief advantages of this method are 1. The nursing is very easy, as there are no weights, &c, and the cradle is the only thing that rests on the bed 2 There is less tendency to movement at the site of fracture than with most other methods, as if the patient moves his body or it should become necessary to move him for the purposes of nursing, the distal portion of the limb and the splint will tend to move with him rather than for the movement to take place at the site of fracture 3 The splint is comfortable and the limb is in the natural resting position of semi flexion. 4 The apparatus is simple and easily applied. Movement of the knee joint can be carried out from time to time by screwing the splint straight with the key while the thigh is supported by an assistant, this can be done without undoing the splint at all. In these days, when the value of early movement and massage in the treatment of fractures is becoming recognised, it is getting more and more necessary to have some method of splinting which will enable one to get at the site of fracture, and to bend the joints without having to remove the splints, and I think that the above method will be found to be an improvement on the older ones. I have to thank Sir William Bennett for his kindness in allowing me to try this method on several cases under his care in St. George's Hospital.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

EXPECTORATION OF A TOOTH THIRTEEN MONTHS AFTER INHALATION INTO THE LUNG

BY W E CARNEGIE DICKSON, B SC, M B, CH.B EDIN

IN the middle of December, 1901, the patient, a marine engineer, aged 28 years, had 12 stumps removed from the upper jaw on two consecutive days, gas being the anæsthetic employed He now recalls the fact that after the second day's operation he experienced a slight feeling of uneasiness connective tissue on the affected side was fuller and contained more fluid than the skin on the opposite side. He did not think that all these cases of empyema went on to a fatal termination but that some of the patients ultimately recovered without operation. He thought that those cases which were due to streptococci very generally proved fatal. He considered that leucocytosis was of some value in diagnosis and referred to two cases in which it was present and after repeated examination pus was at length found.

Dr Pearson in reply said that the evidence obtained from leucocytosis was very uncertain owing to the many complicating factors. He thought that the x rays were of great value although he had not himself used them. He had not examined the urine for albumose. He thought that the infection might in some cases be streptococcic but was much more generally pneumococcic. He had never observed the œdema of the skin on the affected side.

MEDICAL SOCIETY OF LONDON

Hæmorrhagic Typhoid Fever —Spasmodic Contraction of the Pylorus.

A meeting of this society was held on Feb 23rd, Mr A. Pearce Gould the President, being in the chair

Dr. J Kingston Fowler and Mr A. G R. Foulerton communicated a paper on Two Cases of Hæmorrhagic Typhoid Fever. The occurrence of cases of a hæmorrhagic type was recognised in all the infective fevers, in some of which—e.g., typhus fever and small-pox—it was common, while in others, like enteric fever, it was rare. In the two cases which formed the substance of this paper careful bacteriological observations had been made and on that ground they appeared to be worthy of record. The first case occurred in a man, aged 20 years, who was admitted to the Middlesex Hospital under the care of Dr. Fowler on Jan. 6th. On Dec. 27th he suffered from headache and had attacks of shivering On Jan. 20th the appearance of "tender toes" lent support to the view that the case was one of enteric fever in spite of the doubtful results of bacteriological examination and the absence of Ehrlich s reaction. On Jan. 22nd he had an attack of epistaxis, he also vomited blood and passed blood in the urine and a patch of ecchymosis appeared in the lobule of the ear which had been pricked for the blood test. In referring to the bacteriological examination, the negative results obtained from the blood test on Jan. 7th, 14th, and 25th were noted. Pure cultures of bacillus typhosus were, however obtained from (1) a sample of blood and urine drawn off with a sterilised catheter on Jan. 24th, (2) from five cubic centimetres of blood drawn off by a syringe from the basilic vein and (3) blood taken from the spleen after death. Case 2 occurred in a man, aged 23 years, who was admitted on Dec. 16th with a history of 14 days' illness accompanied by pyrexia. On Dec. 23rd blood appeared in the sputum and urine. Ecchymoses appeared in various parts of the skin and there were hæmorrhage from the pharynx and blood in the stools The patient died on the twenty-eighth day of the illness At the necropsy hæmorrhages were found in the pelvis of the kidney and various other situations. Pure cultures of bacillus typhosus were obtained from the heart blood and spleen. In the gall bladder and in some of the muscles the bacillus coli communis was also detected. Turning to the question of etiology which still remained undecided the title of a paper on this subject by Nicholls and Learmonth of Montreal[1] The Hæmorrhagic Diathesis in Typhoid Fever and its Relationship to Purpuric Conditions in General," appeared at first sight to suggest that the authors considered that a close connexion existed between this condition and hæmophilia, but this was not so. In two cases recorded by Eshner and Weisenberg[2] there was a marked history of alcoholism. It had been suggested by Gerhardt[3] that such cases had become more common since the introduction of the cold bath treatment. This was not in accord with the experience at the Middlesex Hospital. These two cases, Dr. Fowler and Mr Foulerton feared, threw but little light upon the pathology of this condition. Case 1 certainly showed that in an example of the most intensely severe form of hæmorrhagic typhoid fever no other organism than the bacillus typhosus might be present and that the mixed infection which had been observed in other cases and which was present in Case 2 was not an essential feature. It appeared from a review of all the facts that as stated by Eshner the hæmorrhages were probably due to changes in the blood or in the vessels, or in both, and that such changes were induced either by the infective or toxic activity of the typhoid bacilli or by both of these factors combined. Mr Foulerton added, as regards the failure to obtain Widal s reaction in either case, that if a case did not give the reaction after 12 days' illness it was either not a case of enteric fever or it was one of extreme severity As to the cause of the hæmorrhagic complication it had been stated that this was due to mixed infections. This was certainly not so in the first of these two cases.—Dr. A. E Wright confirmed Mr Foulerton s remarks relative to the non-occurrence of Widal s reaction in very severe cases of enteric fever He thought the bactericidal power of the blood might have been investigated. This was a point of practical importance and could be easily investigated in the laboratory Turning next to the etiology of the hæmorrhage in these cases he did not believe they had to do with the hæmorrhagic diathesis or with alcoholism, though the ready way in which hæmorrhage occurred after injury in the two cases recorded resembled both of these diseases. Now there was an obvious change in the blood in hæmophilia—namely, diminished coagulability The introduction of typhoid vaccine also diminished the coagulability of the blood and Dr Wright suggested that the cause of the hæmorrhages in hæmorrhagic typhoid fever was an intense intoxication of the blood with the typhoid bacillus. The degree of intoxication could be easily measured by drawing off a drop of blood and counting the number of bacilli per cubic millimetre. A diminished alkalinity of the blood was another cause of diminished coagulability, and he suggested that in future such cases should be tested in both of these respects. In regard to treatment calcium chloride would probably have been of no use. Calcium chloride was only of advantage by combining with the fibrinogen in the blood, but in enteric fever the latter was decomposed and therefore diminished or wanting —Dr Arthur Voelcker asked if the degree of coagulability had been estimated in these cases. He referred to a case of gastric ulcer with hæmorrhage in which the degree of coagulability was markedly diminished.—Dr. Fowler and Mr Foulerton replied.

Dr S. H. Habershon read a paper on Spasmodic Contraction of the Pylorus, its Diagnosis and Treatment. After some preliminary remarks on the normal peristaltic movements of the stomach, he described certain cases of acute and subacute dilatation of the stomach in which spasm of the pylorus was probably present though it might be a matter of conjecture. An important series of cases existed in which some disease, either gastric ulcer or early malignant disease, occurred in the near neighbourhood of the pylorus. The symptoms produced were definite and characteristic, and it was a common occurrence to find that the cause was not recognised. Variable dilatation of the stomach was always present Symptoms of pain, discomfort, or even vomiting were especially manifest in the evening or some hours after food. Pain was usually relieved by food and this was considered an important element in diagnosis. The distinction between these symptoms and those of pyloric obstruction was emphasised. In most cases the diagnosis was confirmed by operation and on this ground it was contended that in the absence of organic obstruction spasm of the pylorus was present. In the treatment lavage was beneficial but gastro-enterostomy produced brilliant results and in non malignant cases was invariably successful. Some cases were related in illustration of the foregoing points Dr Kingston Fowler remarked on those cases in which food relieved instead of increasing the pain. This kind of pain could not be associated with ulcer of the stomach. This pain was different from the sinking sensation which came on about four hours after food and which was due to gastric dilatation. Turning to the treatment, if dietetic means failed operative procedures were often successful. He also referred to severe cases which nothing but gastro jejunostomy could relieve.—Sir Isambard Owen also discussed the character of the pain and agreed with Dr Habershon that the position of the stomach lesion modified the character of the pain a good deal. He thought that the source of dilatation of the stomach due to reflex spasm sometimes lay in the colon when the latter was the seat of a colitis.—Mr Arthur Barker asked how those strictures could be explained which them by a variety of tests. The following cases are interesting as examples of pseudo-diphtheria preceding or following an attack of pneumonia.

CASE 1 —The patient was a boy, six years of age, who suffered from pneumonia accompanied with croupy spasmodic cough, which persisted until after the lapse of 14 days he had an attack of measles running a normal course and attended with but slight tonsillitis. After the measles he had another attack of pneumonia which cleared up in a few days The entire pharynx was subsequently covered with a dense grey membrane which disappeared after 24 hours. No diphtheria bacilli were found in it but only cocci There was otorrhœa preceding and following the attack of measles.

CASE 2 —The patient was a man, aged 37 years, who suffered from pneumonia which was followed by rheumatism While abroad he had contracted dysentery and his bowels were washed out by enemata on account of constipation. His tonsils were slightly affected, a membrane identical with that presented in Case 1 was formed on the pharynx and disappeared within 24 hours, leaving small ulcers. This false membrane, unlike that of diphtheria, was non-contagious

CASE 3 —The patient was a girl, aged six years, a swab from whose throat gave indications of the pseudo diphtheria bacillus when examined at the Jenner Institute by request of the Wandsworth sanitary authority Bronchitis followed

CASE 4 —This patient was a sister of the preceding one, was similarly affected, and had a sharp attack of pneumonia six days afterwards A memorandum from the medical officer of health stated that such cases "end in recovery and are not followed by sequelæ."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Latent Empyema in Infants

A MEETING of this society was held on Feb 24th, Mr ALFRED WILLETT, the President, being in the chair

Dr S VERE PEARSON read a paper on Latent Empyema in Infants He said that empyemata were latent in infants sometimes because of the meagreness of pulmonary symptoms, or an empyema cavity might be overlooked because it was the second of two such cavities Besides these latent empyemata there was another variety of empyema which was particularly likely to be overlooked and it was with this variety that the present paper dealt The cases belonging to this group were characterised by the occurrence of a small sacculated empyema giving rise to progressive wasting and anæmia and to secondary complications of a grave nature The onset usually was gradual and the course of the disease was long An irregularly raised temperature with few symptoms pointing to disease of the respiratory system was common. The physical signs in an uncomplicated case were not well marked, and this paucity of physical signs depended on the size, chronicity and site of the empyema The commonest situation was at the extreme posterior base in the vertebral groove. Here ill defined signs were often obscured by the liver or the stomach interfering with the normal pulmonary resonance The signs varied often from day to day and a slight impairment of resonance to percussion was sometimes the only sign present. The physical signs in cases with secondary pulmonary complications and with complications other than pulmonary were then dealt with. The differential diagnosis from marasmus depended on the fact that digestive derangements were common but were not so severe as to account satisfactorily for the progressive deterioration in the general condition of the patient. A continuously and irregularly raised temperature often reaching 103° F, was not common in chronic wasting children The diagnosis from tuberculosis was often extremely difficult, but the variability of the signs, the signs themselves, and the long delay of the fatal issue in spite of high fever were points of difference between these cases and the majority of cases of tuberculosis in infants. The differential diagnosis of cases with complications from chronic broncho-pneumonia or from purulent pericarditis and other such conditions arising primarily or secondarily to diseases other than empyema was usually very difficult. The secondary effects were, firstly, indirect or toxæmic, the result of the presence of a localised collection of pus, and gave rise to general symptoms—anæmia, wasting, rise of temperature, and pulmonary complications—and locally to thickening of the pleura and fibrosis of the lung, and secondly, direct or bacterial, the result of the spread of the infective agent either locally or by the blood, giving rise (1) locally to purulent pericarditis (and peritonitis) and (2) by blood infection to purulent meningitis, peritonitis, arthritis, and other pyæmic abscesses (and pericarditis) The prognosis was bad, the majority of patients died The cause of death was usually one of the serious complications, those belonging to the bacterial group This high mortality depended partly upon the infrequency of correct diagnosis but also partly upon the difficulties of treatment. The questions to decide with respect to treatment were when to explore, where to explore, and how often Much depended upon the certainty of the diagnosis and the progress of the case. The advisability of exploratory rib resection must be considered in certain circumstances Six illustrative cases of the condition were quoted

Dr F DE HAVILLAND HALL said that the paper drew attention to a class of cases which were frequently overlooked. He himself always feared the possibility of missing a small empyema and indorsed the opinion of Dr Pearson that it was only by repeated examination of the chest in these cases that such an error was to be avoided With regard to the interlobular forms of empyema he considered that diagnosis was impossible, for in many of these cases there was only a thin layer of pus between the lobes of the lung The diagnosis was easier in the basal cases and should always be completed by the insertion of the exploring needle He alluded to a case in which in a debilitated child after pus had been withdrawn from the chest and a rib had been resected the child had died apparently as the result of the operation He considered it advisable in doubtful cases to make many explorations with the needle and he did not think the insertion of the needle gave rise to much pain. He alluded to the advantages to be gained by the use of the x rays in some cases and quoted a case in which this method of diagnosis had been of the greatest advantage. He asked Dr Pearson if albumose had been present in the urine of any of his cases

Dr H S FRENCH mentioned the diagnostic value of the presence of leucocytosis in differentiating cases of empyema from those of tuberculosis He asked Dr Pearson if examination of the blood had been made in his cases

Dr G A. SUTHERLAND said that the difficulty in diagnosis of the form of case described in the paper was very great. He thought that the term "latent" had been used in the paper to embrace more than one class of case. The only forms of case to which he would apply the term "latent" were those cases in which on careful examination no physical signs could be discovered He considered that repeated exploration in cases in which pus was suspected was advisable and that in those cases in which there was reason to suspect its presence resection of a portion of a rib should be performed and every part of the lung could then be explored

Dr F E BATTEN said that he did not think it was possible to make the complete exploration of the lung after the resection of a rib suggested by Dr Sutherland, for in these cases owing to their chronicity the pleural adhesions were considerable and little was gained unless the cavity of the empyema was opened He doubted if the presence or absence of leucocytosis was of much diagnostic value and quoted a case in which there was no leucocytosis but at the necropsy an empyema was found He attached considerable diagnostic importance to the history of an acute or rapid onset in these cases He asked Dr Pearson if any other organism except the pneumococcus had been found in his cases.

Dr H W G MACKENZIE thought that in most cases there was a history of acute onset He was of the opinion that exploratory puncture was often unsatisfactory and that resection of a rib should be done in any doubtful case, and he described two cases in which exploration had failed to find pus but on resection of a rib pus had been found and evacuated

Dr G NEWTON PITT referred to cases of empyema in which the temperature was normal or subnormal throughout the whole course of the disease He thought that in doubtful cases some aid might be obtained by pinching up the skin on the two sides of the chest, when it would be found that the

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens—Some Experiences in the Gynæcological Surgery of the Abdomen.—The Treatment of Uterine Fibro-myomata

A MEETING of this society was held on Feb 11th, Dr JAMES RITCHIE, the President, being in the chair

Sir J HALLIDAY CROOM showed (1) four recent cases of Vaginal Hysterectomy with special reference to Cancer, (2) a Large Fibroid in a case of seven months pregnancy removed by Porro Cæsarean section, (3) a Fibroid Tumour which continued to grow rapidly after removal of the ovaries four years previously, and (4) a Double Hydrosalpinx removed for dysmenorrhœa.

Dr. D BERRY HART showed (1) a Fibroid Tumour developing mainly in the left broad ligament, and (2) a Pyosalpinx in which cultures showed that the pus was sterile.

Dr. G SCOTT MACGREGOR showed a Fibro-sarcoma of the Uterus removed by panhysterectomy The fundus of the uterus occupied the left hypochondrium.

Dr D J GRAHAM showed a large Ovarian Tumour and Uterus removed by hysterectomy

Mr. G ROBERTSON (Dunfermline) showed an Aborting Tubal Mole and a Parovarian Tumour removed from the same patient.

Dr. J HAIG FERGUSON read a paper on Some Experiences in the Gynæcological Surgery of the Abdomen. In one case, where removal of the ovaries for intolerable dysmenorrhœa was undertaken, the operation had to be abandoned, as during the separation of adhesions and drawing the ovary to the surface the patient manifested all the symptoms of death from syncope. She was with difficulty resuscitated and more anæsthetic was given, as it was thought that the syncope was due to a deficient amount. But a second and a third attempt were followed by the same collapse and the operation was abandoned. In extra uterine gestations retention of urine was a prominent symptom and with over-distension of the bladder the case might be mistaken for an ovarian tumour Dr Ferguson had found the opposite tube diseased in several cases, in two containing pus Severe metrostaxis after operation for extra uterine gestation occurred on the fourth day in one case to the extent of endangering life After abdominal operations where no drain had been left in and where there was reason to fear the presence of innocuous fluid it was helpful to raise the foot of the bed so as to spread the fluid over a larger area of peritoneum and thus to hasten absorption and to prevent it accumulating in the pelvis This tilting of the bed lessened any tendency to congestion of the pelvic veins and to oozing If there was a vaginal drain then the head of the bed should be elevated. After a case of abdominal operation he received a message from the medical man in charge that there was evidently peritoneal bleeding Dr. Ferguson replied that the lowest stitch in the wound should be taken out to see if there was hæmorrhage. The next day on taking off the dressings he found a coil of small intestine lying outside the abdomen The medical attendant had taken out one stitch after the other in search of the hæmorrhage and left the wound unclosed. The patient was anæsthetised, the intestines were sponged, and the stitches were reinserted with a favourable result. In two cases keloid developed in the abdominal wound and was found to be best treated by the continuous application of ichthyol collodion.

Dr F W N HAULTAIN read a paper on the Treatment of Uterine Fibro-myomata, with a record of 28 consecutive successful cases of abdominal hysterectomy by the supravaginal method. At the present time they seemed to be in the transition stage between the older practice of medical alleviation and the opposite extreme of excessive surgical zeal begotten of novelty The treatment of uterine fibromyomata might be divided into symptomatic and radical. The former embraced the exhibition of drugs, the employment of electricity, and the removal of the uterine appendages and the latter included the operations of myomectomy and hysterectomy The medicinal treatment practically resolved itself into the exhibition of ergot which, from its action in stimulating the contraction of unstriped muscle, was of special value in bleeding from the uterus. It caused contraction of the arterioles and also of the muscular fibres in the uterine wall, by this means fibro-myomata in the walls of the uterus had their nutrition impeded and they were extruded into the uterine cavity or beneath the peritoneal covering But its effects on the tumour were trivial even after prolonged treatment, so that its value was practically *nil*. Dr Haultain then discussed the electrical treatment which he had used largely He confined his remarks to the after history of a series of 22 cases reported in 1896. He had traced 15 Five of these had reached the climacteric, four remained cured, two had return of the bleeding (one of these expelled a large polypus and the other had three small polypi removed and afterwards oöphorectomy performed), in two the tumour continued to grow to such a size that hysterectomy was recommended, and two had evidently undergone malignant degeneration. Removal of the appendages was undoubtedly of great service in the treatment of hæmorrhage and in inducing a premature menopause and so promoting atrophy of those growths which normally occurred after the climacteric It was restricted in its application by its impracticability in many instances and also by the fact that it failed to produce the expected benefit in about 15 per cent of the cases. In the soft œdematous type of fibroid this treatment seemed to be valueless and should never be attempted. The sphere for this operation had become limited, as the more radical operations were performed with safety and with certainty of cure compared with a 15 per cent. risk of failure. Radical treatment was represented by myomectomy and hysterectomy, either of which might be undertaken by the vaginal or abdominal route. Vaginal myomectomy embraced the removal of stalked growths or submucous polypi and might be very easy if they were only attached by mucous membrane or difficult if they were encapsuled by a thick layer of muscle. Before the days of antiseptics myomectomy for sessile submucous fibroids was most dangerous and rarely attempted. Now it could be undertaken with safety and was chiefly applicable to the cases where the cervix had already been dilated by the downward growth of the tumour Abdominal myomectomy at one time was almost entirely confined to the removal of pedunculated subserous tumours, but was now largely employed for the removal of sessile subserous and interstitial and even large submucous growths. It was, indeed, a debateable question how far conservative surgery warranted them in proceeding on those lines, but some operators had removed as many as 15 nodules from the uterus by this means. The risks of such a prolonged operation and the questionable usefulness of the organ afterwards made him ponder whether the best interests of the patient would not have been served by the removal of such a focus of neoplasms. Hysterectomy or removal of the uterus was called for when the tumour or tumours gave rise to urgent symptoms and could not be efficiently treated by the previous methods mentioned. It might be performed by the vaginal or abdominal route, according to the bent of the operator A number of operators favoured the vaginal method for all tumours less than of the size of a six months pregnancy and based their predilection on the low mortality absence of shock, quicker convalescence, and the avoidance of an abdominal scar Others preferred the abdominal route as giving a better view of the operation area and greater ability to deal with complications as they might arise. It seemed rather a matter of individual selection, Dr Haultain had confined himself to the latter When the abdominal route was chosen two methods might be employed—entire removal of the organ (panhysterectomy) or amputation through the cervix or lower uterine segment (supravaginal method) The adoption of one or other of these methods was usually very much one of individual taste. Those who favoured the supravaginal method supported its adoption mainly on the ground of its greater rapidity and the support given to the pelvic floor by the preservation of the cervix with its vaginal attachment, while the disciples of panhysterectomy advanced its superiority on the principles of peritoneal drainage and the impossibility of secondary cervical cancer Panhysterectomy averaged fully from 20 to 30 minutes longer in its execution than the supravaginal method which itself took from 40 to 60 minutes in an uncomplicated case. Drainage could be easily effected in either method. The chance of secondary malignant disease was too remote to consider, indeed, from statistics the half hour of extra time would on these grounds be better spent in removing the *mammæ* which were more liable to malignant disease than was the cervix. Dr Haultain had performed hysterectomy on 32 cases—28 by the supravaginal method and four by panhysterectomy, two of the were due to an ulcer situated at a considerable distance from the stricture. He expressed a preference for gastro-jejunostomy done without any mechanical appliances.—Dr Walter Broadbent referred to a case of a man who vomited large quantities of fluid and in whom there was great dilatation, and in the analysis of whose stomach contents there was marked increase in the hydrochloric acid. Washing out with weak tannic acid solution produced good results —Dr W J Tyson thought that the cases described by Dr Habershon belonged to a distinct class He advocated rest for their treatment.—The President had seen several of Dr Habershon's cases and in these rest had been tried before operation. Most of the speakers had admitted that spasm of the pylorus could be produced by various kinds of irritation and could result in very considerable dilatation These were bad cases for operation. However, gastro jejunostomy was an admirable means of treating them in many instances Mr A W Mayo Robson's bone bobbin was preferable to any other mechanical means in his opinion.—Dr Habershon replied

LIVERPOOL MEDICAL INSTITUTION

Exhibition of Cases —Chorio-epithelioma Malignum.— Colotomy and Colectomy

A meeting of this society was held on Feb 12th, Mr Rushton Parker, the President, being in the chair

Dr Edgar Stevenson showed a case of Congenital Glaucoma in a child, aged five years, and described in detail the etiology and pathology of the condition. The patient presented all the typical appearances, the eyes being uniformly enlarged with the corneæ 18 millimetres in horizontal diameter The optic discs were cupped and atrophic, and the visual fields were much contracted. Out of 65 000 patients seen in recent years at the Liverpool Eye and Ear Infirmary the disease had appeared four times.—Dr K A. Grossmann and Mr C G Lee commented upon the case

Mr J E McDougall showed a case of Adherent Soft Palate which had been successfully treated by a new method. A thin plate of metal was attached to the patient's artificial tooth plate and to the extremity thereof a tube was soldered. The tube was passed through an opening in the soft palate made to admit its passage. Healing had taken place and the edges had become covered with epithelium The patient removed and replaced the arrangement as readily as she did the ordinary tooth plate before any addition was made to it. When no tooth plate was worn a carrier for the tube could be fixed to the teeth. The apparatus gave no trouble and the result was most satisfactory Nose breathing was carried on comfortably the sense of smell had returned and that of taste had regained its full value.—Dr Philip Nelson spoke with regard to the case.

Mr G A. Hawkins Ambler read a note on Chorio-epithelioma Malignum. He thought that Marchand's work had proved the origin of the growth from the whole of the epithelial covering of the chorionic villi The history of a woman (aged 39 years and the mother of 12 children) who had suffered from the disease was given in detail. The last of three abortions occurred in May, 1900, and was accompanied by severe hæmorrhage The uterus was curetted and packed. Six weeks later, on the occurrence of furious bleeding, the uterus was again packed and subsequently was thoroughly scraped with a sharp spoon. The uterus was smooth and measured three inches On June 17th, 1902, a uterine swelling was present extending to within one and a half inches of the umbilicus. There was a steady chocolate-coloured discharge and the patient was anæmic and breathless No radical treatment was possible No regular post-mortem examination was obtained and no metastatic growths were found. The case was interesting owing to the long interval since the last pregnancy and the thorough curettage then done. Packing with gauze and adrenalin solution had been less effective than with gauze soaked in hamamelis extract.

Mr F T Paul read a short paper on Colotomy and Colectomy He considered the former operation was becoming more popular chiefly owing to the better artificial anus now generally obtained In regard to the latter he still strongly advocated bringing the ends of the bowel out with subsequent restoration of continuity in preference to end-to-end union The latter was more satisfactory to the surgeon when the patient recovered but the risk was much greater Patients illustrating the results of the operations were shown and also the plug and belt used by Mr Paul for colotomy cases.—The President Sir William M Banks, Dr W Alexander. Dr H Briggs, Dr F Heatherley, and Mr K. W Monsarrat spoke and Mr Paul replied.

Exhibition of Specimens Photographs, and Drawings —Ringworm of the Cat infecting Children.

A meeting of the Pathological and Microscopical Section of this society was held on Feb 19th, Mr Rushton Parker, the President, being in the chair

Dr W Alexander exhibited (1) specimens from a case of Abscess of the Liver following Dysentery, and (2) the Organs of a second case of Liver Abscess secondary to an Appendicitic Abscess

Dr R G Henderson exhibited the Anterior Half of a Tongue spontaneously amputated by a rapid ulcerative process which examination showed to be epitheliomatous.

Dr R. J M. Buchanan showed specimens of Bilharzia Hæmatobia from Urine

Sir William M Banks exhibited sections from a case of Spindle-celled Sarcoma of the Breast and photographs of two patients with large Tumours of this description He remarked that they were not, as a rule, clinically malignant and for the most part there was no recurrence after removal.

Mr G P Newbolt showed (1) a Liver with a Tropical Abscess from a dysenteric patient, and (2) a Tuberculous Kidney in the early stage of the disease successfully removed by lumbar nephrectomy

Mr C H B Shears and Mr E M Stockdale showed a Melano sarcoma of the Choroid which had perforated the sclerotic, the growth was of the spindle-celled variety

Mr C G Lee and Mr Stockdale showed sections from two cases of Epithelioma of the Pinna.

Dr J Wiglesworth showed (1) a Brain with Numerous Melano sarcomatous Nodules, these were merely part of a very wide diffusion of similar deposits all over the body, and (2) a specimen of Horse-shoe Kidney

Dr J E Gemmell exhibited the Ovaries of a patient, both organs being affected with carcinoma and cystic disease.

Mr R J Hamilton showed an Eyeball containing a Leuco-sarcoma of the Choroid and microscopical sections of the same.

Dr R. C Dun showed a Sarcoma of the Kidney removed by operation from a child aged three years.

Sir William Banks exhibited a number of casts, drawings, and specimens of Parotid Tumours He remarked that with regard to the innocent variety the commonest were of the mixed type. Of the malignant varieties he thought that sarcoma was rare but that carcinoma was not at all uncommon and he showed a patient from whom he had removed a large growth of this type. The intention of the note was to point out the frequency with which apparently innocent parotid tumours become malignant. Details were given of three cases in which this had occurred in spite of the fact that the growths had remained small, painless, and moveable for long periods. He thought that there should be no delay in the removal of parotid tumours however harmless they might be in appearance He had been taught to consider parotid tumours as among the least dangerous in the body, but he now regarded them with grave suspicion. He considered it undoubted that there was a great general increase in cancer among civilised nations and it seemed not improbable that this proneness to degeneration in parotid tumours was part and parcel of that tendency

Dr Leslie Roberts read a note on an example of Trichophyton in the Cat The animal was infected in Egypt, 20 days after leaving this country the cat was taken to a house where there was a large family of children. A few days later ringworm was observed on the neck of the eldest daughter, within a month 14 individuals were accidentally infected with the fungus as were a kitten and a Skye terrier The infection was subsequently communicated to a school

The following members took part in the discussion of the specimens the President, Dr T R. Bradshaw Dr Alexander, Mr Hamilton, Mr W Thelwall Thomas, Mr F C Larkin, Mr Stockdale, Dr Buchanan, and Mr K W Monsarrat

Nipple in a woman, aged 66 years The patient was under the care of Mr C T Dent at St. George's Hospital The disease commenced 18 months ago as a red spot just above the nipple and now showed an oval red patch surrounding the nipple one and a half inches by one inch in diameter The margin was well defined and the surface was covered with fine scales. There was distinct induration but there were no enlarged glands in the axilla.—Mr E. W Roughton said that Paget's disease was so frequently a precursor of carcinoma of the breast that he considered it the duty of the surgeon to remove the breast with a wide area of skin and to clear out the axillary contents.—Mr F Jaffrey and Mr Campbell Williams both agreed with the diagnosis and recommended radical treatment —Dr E. Cautley showed a man, aged 28 years, with Pseudo-hypertrophic Paralysis. Apparently no symptoms were noted until seven years ago He stumbled a little and had difficulty in getting upstairs. The calves measured 17½ inches in diameter and were very hard. The knee jerks were absent The vasti were a little wasted but no other muscles were involved. The case was interesting on account of the age of the patient, the limitation of the disease, and the comparatively slow progress —Dr James Taylor remarked that the case was very interesting as forming a link in a chain. He himself had known one case in which the signs and symptoms had only developed at the age of 18 years. Previously to this the patient had not only been able to walk but had actually been an athlete and had won prizes for running Another case he had seen at the age of 43 years and the patient had never been able to run. He remained practically unchanged, a typical case of pseudo-hypertrophic paralysis, until his death from pneumonia at the age of 50 years. These cases seemed to illustrate a condition in which there was probably an inherited weakness or defect in the muscular tissue, which might become obvious at any age and progress with varying rapidity —Mr Roughton showed a youth with Dislocation of the Right Shoulder and Right Hip and with deformities of many bones, including the lower jaw There were scars in the region of all the bones affected and the condition was probably due to chronic septic infection during infancy —Mr Jaffrey showed a specimen of a Testicle which before removal had been diagnosed by everyone who saw the patient as one of tuberculous epididymitis but which proved on removal to be rapidly growing sarcoma A secondary deposit in the lumbar glands was recognised within a fortnight of removal of the organ.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY —A clinical evening of this society was held on Feb. 12th, Dr G R Murray, the President, being in the chair —The following were some of the cases exhibited —Dr H. E Gamlen showed (1) cases of Lupus treated by x rays and ultra violet rays, some of the patients being apparently cured and others improving, (2) Rodent Ulcer of the Face cured after 90 minutes' application of the x rays, and (3) Scirrhus of the Breast (?) cured by the x rays He also showed a case of Epithelioma of the Tongue supervening on Gumma, this patient refused operative treatment. At first with x ray treatment there was distinct improvement but now the disease was rapidly becoming worse.—The President showed cases of (1) Paralysis Agitans, (2) Aneurysm of the Aorta, and (3) Insular Sclerosis.—The President and Mr J R. Morison showed a case of Cirrhosis of the Liver treated by operation and cured.—Mr A M. Martin showed a case of Marked Varicose Condition of the Veins of the Left Leg in a man aged 60 years with a small ulcer over the internal malleolus. The treatment proposed was excision of the internal saphena in the leg and ligature also at the saphenous opening —Mr G W Ridley showed (1) a patient after Removal of the Upper Jaw and part of the Nose for Malignant Disease, and (2) four patients after Excision of the Tonsil for Sarcoma.—Dr J Limont showed several examples of Skin Disease (lichen, erythema purpureum pityriasis rubra &c.) —Dr T Oliver showed a case of Aneurysm of the Arch of the Aorta treated by gelatin injection.—Dr Oliver and Mr. Morison showed a woman aged 41 years whose Uterus with the Infant, was removed by Abdominal Section, almost at term for Carcinoma of the Cervix.—Dr W C Beatley showed a case of Exophthalmic Goitre in a girl, aged ten years.—Dr R A Bolam showed a patient with Natural Development of Collateral Venous Channels in Cirrhosis of the Liver —Mr. T G Ouston and Dr Young showed a patient after operation for Congenital Torticollis, together with apparatus for maintaining correction —Mr Morison showed cases of (1) old Tuberculosis of the Rib with affection of the overlying skin, (2) Irremoveable Carcinoma of the Breast treated by Oöphorectomy with improvement, (3) Paralysis of the Brachial Plexus following Dislocation of the Shoulder nine months previously, and (4) Extensive Epithelioma of the Chin with marked Gland Infection treated by ligature of both external carotids

LARYNGOLOGICAL SOCIETY OF LONDON —A meeting of this society was held on Feb 6th, Dr P McBride, the President, being in the chair. —Mr R Lake showed (1) a Microscopic Specimen of Pseudo pachydermia from the Processus Vocalis in a tuberculous subject, and (2) a case of Tuberculous Laryngitis.—Mr Charters J Symonds showed a case of Paralysis of the Left Vocal Cord, the result of lead poisoning in a girl, aged 18 years. The patient exhibited the usual paralysis of the limbs and a marked blue line on the gums The rarity of the laryngeal affection was commented upon.—Sir Felix Semon drew attention to the fact that the form of paralysis varied with the poison, lead having a selective action on the abductors.—Dr L. H. Pegler showed a Septotome for Moure's and other Operations for Deflected Septa.—Mr P R. W de Santi showed a case of Unilateral Enlargement of the Right Side of the Thyroid Gland in a woman aged 50 years. There was great displacement of the larynx and trachea and the patient had had attacks of dyspnœa. Mr de Santi proposed to remove the right half of the thyroid.—Sir Felix Semon showed a case of Tabes with early and unusual implications of various cerebral nerves in which the chief features of interest were (1) complete paralysis of the soft palate in spite of which the swallowing of fluids did not produce regurgitation when the patient drank slowly, (2) non-implication of the tongue until a few days previously; (3) the vacillations of the symptoms, the paralytic phenomena being distinctly more marked on some days than others, and (4) the absence of laryngeal crises —Dr J Donelan showed a case of Ankylosis of the Left Crico-arytenoid Articulation in a woman, aged 23 years.—Dr J Dundas Grant showed a case of Persistent Œdema of the Larynx in a middle-aged woman. The case was discussed by Sir Felix Semon, Dr. F de Havilland Hall, Dr A. Brown Kelly and Dr. Mackintosh.—Dr W Hill showed a case of Tuberculous Disease of the Larynx with intra arytenoid growths, but with no evidence of pulmonary involvement —Other specimens were shown by Mr Hunter Tod, Mr W H. B Stewart, Mr F J Steward, Dr Brown Kelly, Mr E B Waggett, and Dr E. Furniss Potter

BRISTOL MEDICO-CHIRURGICAL SOCIETY —The fifth meeting of the session of this society was held on Feb 11th, Mr G Munro Smith being in the chair —Dr E. Markham Skerritt showed a case of Anomaly of Blood-vessels.—Dr H Waldo exhibited the following cases (1) Two cases of Lupus Vulgaris treated by the Finsen light; (2) a case of Folliculitis, and (3) a case of Lupus Erythematosus —Mr A W Prichard showed a Simultaneous Amputation of both Breasts and Removal of Infected Glands in both Axillæ.—Dr J E Shaw showed a case of Scleroderma with Pigmentation and Muscular Atrophy —Mr J Paul Bush, C M G, exhibited the following cases (1) A Sequestration Cyst of the Cheek, (2) Unilateral Coxa Vara, (3) a patient after Removal of the Clavicle for Sarcoma (the specimen was shown), and (4) a patient after Removal of the Scapula for Sarcoma (the specimen was shown in this case also) —Dr J Michell Clarke showed (1) a case of Graves's Disease, with Unilateral Exophthalmos and a Patch of Hyperidrosis on the Leg; (2) a case of Intracranial Tumour, (3) a case of Thoracic Aneurysm with Indirect Signs, and (4) a case illustrating the Treatment of Pancreatic Diabetes by Opium —Mr F R. Cross showed (1) two cases of Operation for High Myopia, and (2) a case of Thiersch Grafting for Severe Burn of the Face involving both Eyelids.—Dr A Ogilvy exhibited a case of Ruptured Choroid showing the entrance of one of the ciliary arteries through the sclerotic.—Dr C H. Walker showed (1) a case of Cyst of the Iris, and (2) a case of Organised Lymph in the Anterior Chamber from a wound of the cornea nine years previously —Dr R. G P Lansdown showed (1) a case of Amputation of the Breast with Removal of a Rib, and (2) a case of Atrophic Scirrhus of the Breast with Secondary Deposits.—Dr F H. Edgeworth exhibited cases of (1) Chorea, (2) Acromegaly, and (3) Achondroplasia.—Mr T Carwardine showed a case of Perityphlitic Actinomycosis.—Mr H. F Mole showed (1) a case of Injury to the Testis, and (2) a case of latter were by selection for experience and two on account of sarcomatous degeneration of the growth. The operation was undertaken in the 32 cases for hæmorrhage in 20, pressure in seven, abdominal prominence in three, pregnancy in one, and malignancy in one. Pathologically they might be classified as multinodular 20, calcareous one, œdematous seven, cystic one, with carcinoma one, and sarcomatous two. An interesting point in the case complicated with pregnancy was the fact that the placental site was placed over the seat of the tumour; this probably accounted for the fact that an attempt to induce abortion was futile, the tumour preventing contractions of the uterine wall on the placental site. The calcareous growth was removed from a patient, aged 69 years, on account of painful pressure. In operating Dr. Haultain preferred to ligature both ovarian and uterine arteries before amputation of the uterus in simple cases. As far as possible he attempted to ligature the uterine arteries at the point where they commenced to ascend the side of the uterus, transfixing a small portion of the uterine wall and including it in the ligature; by this means all chance of tying the ureter was avoided. He did not pay any attention to disinfection of the cervical canal and did not attempt to avoid passing the sutures through it as recommended by some operators. Out of the 32 cases one only proved fatal; it was a case where panhysterectomy was performed for a very large sloughing intra-uterine tumour and death was due to septic poisoning. All the other 31 patients recovered. There was a singular absence of shock after the operation even in patients reduced by extreme bloodlessness. Convalescence was much more rapid than even after a simple ovariotomy. If the ovaries appeared to be healthy Dr. Haultain left them to obviate the harassing symptoms of an artifically induced menopause. If a fibroid gave rise to no symptoms it should be left alone as far as surgical treatment was concerned; the possible chance of its becoming malignant was too remote to receive consideration. On the other hand, whenever marked symptoms appeared treatment was urgently demanded, as the general tendency was for them to continue and to become aggravated unless the climacteric supervened. In suitable cases Dr. Haultain considered that electricity should have more deference given to it as it could be used in cases where the patient resolutely refused operation. It seldom failed in interstitial tumours. Removal of the ovaries failed in 15 per cent. of the cases, whereas the radical operation effectively cured. The mortality with the latter was 6 per cent. according to some statistics, but that was questionable.

These papers were discussed by Sir J. HALLIDAY CROOM, Dr. HART, and Dr. J. LAMOND LACKIE.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Exhibition of Specimens.—X Ray Photography.

A MEETING of this section was held on Feb. 6th, Professor ALEXANDER FRASER being in the chair.

Dr. E. H. TAYLOR showed two specimens of the Newly born Infant to demonstrate the Topographical Anatomy of the Stomach and other Abdominal Viscera.

Professor FRASER showed two cases of Congenital Absence of the Left Lateral Half of the Diaphragm. One case occurred in a male fœtus which was at about the fourth month and was otherwise perfectly normal. The under surface of the left lung lay upon the suprarenal capsule, the stomach, and the left lobe of the liver. The left free margin of the central part of the diaphragm ran as a strong band from front to back, slightly external to the pericardial sac and above the left suprarenal capsule and kidney. The other case occurred in a full time female fœtus and was only one of many abnormal features that were present. The left pleural cavity contained the lung and several coils of the small intestine (which was well developed), and the left lobe of the liver projected into it. This cavity also communicated with the pericardial sac, the upper half of the left wall of this sac being absent. Between the two pleural sacs dorsal to the heart, but more to the right than the left, a large cavity was found containing a well developed stomach, pancreas, and spleen.

Dr. TAYLOR and Dr. E. J. M. WATSON made a communication on the Value of X ray Photography in connexion with the Structure of Bone. Dr. Taylor dwelt specially on the temporal bone in connexion with operations for the results of suppurative middle-ear disease. Dr. Watson exhibited many beautiful skiagrams showing the structure of different bones.

Dr. W. S. HAUGHTON made a communication relative to the Anatomy of the Skull Stereoscopically Demonstrated by the X Rays. He said that the difficulty of interpreting a single skiagram arose from several causes. The x ray picture was an example of uniplanar projection of multiplanar objects. This caused superposition of shadows. Then the fact that the x rays formed a diverging cone caused magnification and obliquity distortions. These sources of inaccuracy in the "single picture" were eliminated by the beautiful stereoscopic method of Roentgen photography first described by Mr. J. Mackenzie Davidson. By this method a reproduction of the skull could be obtained, perfect in contour and perspective. Dr. Haughton then showed by diagrams on the blackboard how all the above-mentioned sources of inaccuracy were eliminated in the stereoscopic method and afterwards in the reflecting stereoscope showed prints of the base of the skull and lateral views in which general points were well demonstrated, including the relations of the groove for the lateral sinus to the mastoid air cells, the mastoid emissary vein, the internal auditory meatus, the external auditory meatus, the cochlea, the semi-circular canals, the canal for the internal carotid artery, and the foramina in the base of the skull.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 11th, Mr. H. A. G. Brooke, the President, being in the chair.—Dr. Joshua J. Cox showed a boy, aged nine years, a typical achondroplasic dwarf. The stunted and deformed condition of the long bones of the limbs, the "trident hands," and the narrowed pelvis were very evident. A series of skiagrams of the skeleton of this boy was exhibited together with skiagrams of the skeleton of a dwarfed child suffering from infantile myxœdema and of a normal child aged nine years.—Dr. Charles H. Melland and Dr. D. Ord gave a demonstration, illustrated by coloured micro-photographic lantern slides, of the Blood in Health and Disease. The former described the process of fixing and staining the films and explained that although a thorough knowledge of the blood could only be obtained by making a count of the corpuscles, red and white, and an estimation of the hæmoglobin, with a thorough inspection of a large area of blood film, it was still possible with care to select portions of the film which appeared, as it were, an epitome of the condition met with, as well as to pick out special fields which showed the presence of peculiar or unusual conditions of the corpuscles. Such a procedure had been followed in the present instance; the selected fields had then been photographed and the corpuscles coloured by hand, the colours of the stained films being reproduced as closely as possible, and in those cases in which there was any ambiguity in the uncoloured photograph the colouring was undertaken with the original microscopic field at hand for comparison and guidance.—Mr. E. Stanmore Bishop showed two Tubo-ovarian Cysts removed from a woman, aged 34 years, the mother of one child, 10 years old. The os had been split. There were no symptoms for four years and then there was flooding for seven weeks, which was followed by metrorrhagia more or less ever since. Physical signs pointed to fibromyoma. Both cysts were firmly adherent and had developed under pressure. After discussing the three modes of origin of tubo-ovarian cyst and Mr. J. Bland Sutton's views on the production of hydrosalpinx Mr. Bishop mentioned a second case and showed the specimen, in which the same symptom of metrorrhagia had accompanied the development of a cyst under pressure of firm adhesions which had converted Douglas's pouch, in which it was found, into a closed cavity. Both patients recovered perfectly.—Dr. G. Robertson Mill showed a Preparation from a fatal case of Acute Obstruction. The terminal loop of the ileum was strangulated by an appendix which completely encircled it and the extremity of which was in turn imprisoned between the free border of the meso appendix and the termination of the ileum.—Dr. J. S. Bury showed a specimen of Sarcoma of the Lung which caused a pulmonary systolic murmur.—Other preparations were exhibited as card specimens.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this society was held on Feb. 19th, Dr. W. Winslow Hall, the President, being in the chair.—Mr. T. Crisp English showed a case of Paget's Disease of the Left section on Yaws Pellagra, Lathyrism, Tinea Imbricata, and Pinta. Those who have practised or travelled in the East cannot fail to be reminded of what they have occasionally seen there and will be best able, perhaps, to appreciate their fidelity to nature. It should be added that in addition to these illustrations the work contains some excellent maps and plates

---

A Treatise on Surgical Therapeutics of Domestic Animals By P J CADIOT, Professor, and J ALMY Adjunct, in the Veterinary School of Alfort. Translated by A. LIAUTARD M.D V M New York William R. Jenkins. Vol. I., Part 3. Pp. 130

THE names of the authors of this little volume are a sufficient guarantee of the value of the original work to the veterinary practitioner but the translation is somewhat disappointing to English readers. Most curious terms, unintelligible to English ears, are to be found in many places and many new words have been coined For example, anthrax is divided into "bacterian" and "bacteridian," the term "bacterian anthrax" being applied to the disease known as "blackquarter," a malady which is now known by every veterinarian to be due to its own specific organism and not in any way to be connected with the bacillus anthracis. We read on pages 209 and 210 that farcy is "a morvo-farcinous infection and under all its forms susceptible of cure ," and the word "malleinization" has been coined to express the use of the mallein test. Under Tuberculosis "a local relapse implies a new exeresis" and a "bacterioscopic" examination is said to establish the diagnosis of this disease with certainty The following paragraph on page 212 is quite unintelligible to the average mind and reads like a word puzzle "Fungous arthritis should be treated by immobilization of the joint and injections of iodoformed vaseline into the fistulaer those of chloride of zinc (1–10) into the zone neighbouring the morbid center (-cleragenous method of Lannelongue) ' We read (page 215) that "in man some observations have been mentioned which seem to establish the *contagiosity* of cancer,' and as headings of chapters the diseases known as "Stickfasts," "Contractures,' "Nerf-férure," and ' Amyotrophies" certainly require explanation. Perhaps, however, the most curious and erroneous statement is to be found on page 240 the chapter being headed ' Furuncle-Anthrax.' The statement is made that "ordinary *anthrax* is but a voluminous, diffuse furuncle, extending to the subcutaneous connective tissue, or an inflammatory tumour formed by confluent furuncles. Like the generality of human surgeons and of foreign veterinarians, we have no hesitation, notwithstanding the etymology, to apply this word to lesions which have nothing in common with anthrax (charbon) Bacteriology has shown that furuncle and anthrax are promoted in man by the same micro-organism—the staphylococcus pyogenes aureus." We regret that neither the translator nor the publisher can be congratulated on the result of the good intentions, expressed in the preface, to benefit the "English-reading practitioners as well as the students of our veterinary colleges '

Elementary Biology Descriptive and Experimental By JOHN THORNTON, M.A. London Longmans, Green and Co 1902. Pp 270 Price 3s 6d

THE volume before us forms a recent addition to the well known Practical Elementary Science Series published by Messrs. Longmans, Green, and Co , and is intended mainly for teachers who are preparing for the examinations of the Board of Education." The author in his preface exoresses the hope that "besides being serviceable to students preparing for the examinations mentioned the book will prove useful to all teachers engaged in promoting nature study " The work may be roughly divided into three parts dealing respectively with (1) the problems common to both plants and animals, (2) botany, and (3) animal biology Of these the botanical portion is the least satisfactory

In a biological work which is to serve as an introduction to a knowledge of the two constituent sciences, it is a mistake, we think, to enter at all deeply into a consideration of the structure of plants—that is to say, histological details which can only be made out with the aid of a compound microscope. By all means let the structure of plants be dealt with, but only so far as can be ascertained by the use of a good lens. It is a matter for regret that there is too great a tendency to neglect morphological botany, notwithstanding the fact that it may be made one of the most interesting and educative of sciences for beginners. It is not by any means suggested that Mr Thornton is responsible for this, for inasmuch as he has set himself the task of writing a book suitable for a certain examination he must perforce follow the prescribed work The matter is rather to be referred to those to whom the syllabus is due. On the other hand, the author is responsible for his statements of facts, these are generally both clear and correct, but this is not invariably the case For instance, in paragraph 13 the following observations concerning cellulose occur "It forms the fibrous framework of all plants, as well as the envelope round starch grains. Cotton, wool, flax, and hemp consist of cellulose mixed with small quantities of mineral matter, while woody fibre is modified cellulose with colouring and mineral matter." Further, several statements regarding fibres need much improvement, for example, on p. 57 we find that the bast fibres (presumably of the sunflower) are described as having cellulose walls, again, on the following page the conduction of water is ascribed to the wood fibres, and, further on p 133 the following occurs 'The small black seeds of the cotton plant are also provided with fine white hairs or fibres for dispersal. These fibres provide the cotton of commerce " Besides structure, the botanical portion of the book deals also with the morphology and physiology of plants.

That part of the work which is devoted to animal biology is chiefly concerned with the outlines of the structure and physiology of the human body The cat is taken as an example to illustrate "structure in relation to movement as represented by some common quadruped. ' Experiments are interspersed throughout the text and very generally are suitable, it may be pointed out, however, that the following experiment as it stands (p 90) is not conclusive "Collect water passed through some soil in a flower pot. Filter it to remove suspended matter and then evaporate the clear solution in an evaporating dish. A residue is left, showing that soluble matter was taken up from the soil by the water that has passed through it." The work is illustrated by 180 figures, some of which have been specially drawn, while several have been obtained from various sources. Many questions and exercises, with occasional hints and explanations, form a sort of appendix. In conclusion, we are of opinion that, with the exception of those points of weakness to which attention has been drawn, the work will prove useful to those for whom it is intended.

LIBRARY TABLE.

Memoirs and Letters of Sir James Paget Edited by STEPHEN PAGET, one of his sons. Third Edition (eighth impression). With a Postscript by Sir THOMAS SMITH. London Longmans, Green, and Co. 1903. Pp 465. Price 6s net —This the third and cheaper edition of a remarkably interesting work, of which we reviewed the first edition in THE LANCET of Oct. 12th 1901, p. 982, has the advantage of a postscript by Sir Thomas Smith who as he himself says, Duchenne's Birth Palsy —The cases were discussed by the members present.

KIDDERMINSTER MEDICAL SOCIETY —A meeting of this society was held on Feb 6th, Mr J Lionel Stretton, the President, being in the chair —The President showed a large Appendix Cæci removed from a man, aged 25 years, whose peritoneum was found to be infiltrated with miliary tubercle.—The President also showed two patients upon whom he had operated for Anthrax. One of them was a woman, aged 31 years, in whom the pustule appeared on the cheek on Dec. 9th and was excised on the 15th The other patient was a man, aged 44 years, on whose neck the pustule appeared on Jan. 18th and was excised on the 24th. Both patients were treated with powdered ipecacuanha internally and externally and both made good recoveries. The President also mentioned the case of a man who died about two months previously in whom the pustule was not removed He insisted on the importance of immediate excision and advocated the use of ipecacuanha internally and externally Though he was not convinced as to its specific action he had so often seen cases recover under its use that he felt bound to use it until its value was disproved —Mr E Stanley Robinson showed a man, aged 59 years, who was considered to be suffering from Thoracic Aneurysm —Dr W L. Maccormac read notes of the case of a man, aged 55 years, who was admitted into hospital suffering from Dyspnœa after exertion and a harsh, "brassy" cough. The laryngoscope showed some thickening at the upper end of the larynx and the case was diagnosed as one of malignant disease of the larynx Chloroform was being administered in order that tracheotomy might be performed for the relief of the dyspnœa when the patient died from asphyxia —Dr Bertram Addenbrooke read a paper on Medical Electro therapeutics.

ÆSCULAPIAN SOCIETY —A meeting of this society was held on Feb 20th, Dr Thomas G Stevens, the President, being in the chair —Dr B G Morison opened a discussion on Infantile Diarrhœa (Zymotic Enteritis) The cause of the condition he held to be the ingestion of organisms with food. The clinical features and pathology were similar to those of Asiatic dysentery The green coloured stools were due, he thought, to oxidation of a deficient quantity of bile in the intestine This seemed to be confirmed by the altered colour of the stools through the stimulus of rhubarb or euonymin to the normal yellow The essential item in treatment was to avoid fermentation of milk, and this was most simply done by abstinence from milk for 24 hours or more. Albumin-water, meat-juice, or whey might be given advantageously Rest in bed was preferable to being nursed. The drugs most serviceable were salol as an antiseptic, bismuth and chalk as astringents, and ipecacuanha as a cholagogue.—The President said that he had seen very good results in these cases from giving small doses of the solution of perchloride of mercury and again from glycerine of carbolic acid.—Dr S P Huggins said that he had found benefit from feeding on unsweetened condensed milk and giving sodium salicylate.—Dr Morison replied.

HUNTERIAN SOCIETY —A meeting of this society was held on Feb 11th, Dr A L Galabin, the President, being in the chair —The annual oration was delivered by Mr T H. Openshaw, C M.G The subject chosen was "John Hunter, his Influence on Surgery, with some remarks on the Treatment of Appendicitis."—The following officers were elected —President, Dr S H. Appleford, vice-presidents, Dr W A. Dingle, Mr F Wallace. Mr J Adams, and Mr J H Targett, treasurer, Dr R. Hingston Fox, trustees, Mr F M. Corner, J P, Mr F Gordon Brown, and Mr R. Clement Lucas, honorary librarian, Dr T H Arnold Chaplin, orator, Dr J F Woods, secretaries, Dr T Glover Lyon and Mr H L. Barnard, editorial secretary, Dr E W Goodall, council, Dr H R. Andrews, Sir Hugh R. Beevor, Dr A T Davies, Dr R Fortescue Fox, Mr A W Galloway, Dr Galabin, Mr F R. Humphreys, Dr Ernst Michels, Dr W Rawes, Dr J W Oliver Dr F J Smith, and Dr Woods, auditors, Mr F Gordon Brown, Dr Smith, Dr Davies, and Dr Woods.

VACCINATION IN BRISTOL.—During 1902 there were 6898 primary successful vaccinations performed in Bristol as compared with 5776 in 1901

Reviews and Notices of Books.

The Diseases of Warm Countries a Handbook for Medical Men. By Dr B SCHEUBE, State Physician and Sanitary Adviser, Greiz, late Professor at the Medical School in Kioto (Japan) Translated from the German by PAULINE FALCKE, with addenda on Yellow Fever by JAMES CANTLIE, M.B Aberd., F R.C S. Eng, and on Malaria by C W DANIELS, M.B Cantab, M.R.C S Eng Edited by JAMES CANTLIE, M.A, M.B. Aberd., F R.C.S Eng, D P H., Lecturer at the London School of Tropical Medicine, Surgeon to the Seamen's Hospital Society, Albert Dock Hospital, Lecturer on Applied Anatomy, Charing Cross Hospital Medical School, London, Consulting Surgeon to the Alice Memorial Hospital, Hong Kong With all the original Coloured Maps, Charts, Illustrations, &c., together with many additional Plates from the *Journal of Tropical Medicine* Second revised edition. London John Bale, Sons, and Danielsson, Limited. 1903. Pp 594. Price 30*s* net

WE may say at once that this is a full and, so far as is possible considering the many fresh additions that are being constantly made to our knowledge, a very complete book. The editor is quite justified in calling attention in his preface to the range of knowledge, general accuracy, and scientific spirit which characterise Professor Scheube's work and to the care and labour involved in the production of a book of this kind. The desirability of reproducing it in English will be admitted by all who are interested in tropical diseases and in the progress of scientific medicine. The translation of Professor Scheube's work has been successfully carried out by Miss Pauline Falcke

As affording a general idea of the nature and scope of this handbook of the diseases of warm countries we may say that the subjects embraced in it are arranged in six groups—general infectious diseases, diseases caused by intoxication, diseases due to animal parasites, organic diseases, cutaneous and local diseases, and the cosmopolitan diseases in the tropics, with an addendum to the chapter on yellow fever in which Mr Cantlie, who edits the handbook, describes the results of the latest investigations of the United States Army Commission in Cuba, and another addendum to the chapter on malaria by Dr Daniels The method generally followed in dealing with the subjects under consideration is a systematic and good one. It consists of a definition of the disease, its synonyms, history and geographical distribution, etiology, symptomatology, varieties, pathological anatomy, diagnosis, prognosis and treatment, supplemented by a carefully compiled bibliographical list of the literature bearing upon the subject It would be impossible, of course, within any reasonable limits to travel over the ground occupied by an exhaustive treatise of this kind. We must content ourselves by referring to a few of the chapters which we have read with most interest. The volume opens with a consideration of the general infectious diseases and begins with Plague This chapter summarises the facts connected with that disease, together with the results which have accrued from recent experience and scientific investigations during the modern history of epidemic plague

The chapter on Mediterranean Fever is a brief one, but it nevertheless gives an accurate description of what is known. The Malaria of Warm Countries is discussed in a long and carefully written chapter and with the excellent addendum by Dr Daniels, medical superintendent of the London School of Tropical Medicine, may be profitably studied The chapters on Beri beri, Leprosy, and Filarial Disease are admirably illustrated, indeed, the illustrations throughout the volume are, generally speaking, very good. Many of them are from the *Journal of Tropical Medicine* or are new, as will be seen if the reader will turn to the all The medical reader, too, will find little that is faulty or deficient in Miss Sturge's account and explanation of the "healing" side of Christian Science. What Mark Twain's admirable and irresistible articles in the *North American Review* do for the average man and woman of the world in the way of showing the real nature of Christian Science, its grossly material side and its commingled spiritual excellences, that Miss Sturge's book will do for the thoughtful reader and the student of religion, if only such persons can endure the ordeal of reading a just account of Christian Science.

New Inventions.

IMPROVEMENTS IN VAGINAL TUBES

IN THE LANCET of Dec 4th, 1897, p. 1463, I described a new form of vaginal tube the chief characteristics of which were a bulbous end and a comparatively thin rigid shaft. This scientifically adjusted and practicable instrument offered the one disadvantage of the bulb being hollow It has hitherto been considered by gynæcologists and obstetricians that all vaginal tubes must of necessity have a number of perforations terminating into the central canal The common red gum elastic tubes, used hygienically by women, as well as all glass tubes used by surgeons, have been made in this way A tube with several very small perforations, however, cannot easily be kept clean. I have found that, provided a tube be bulbous, as seen in Fig 1, only one bore is necessary, running from end to end, particularly if this bore enlarges at its extreme end, as seen in Fig 2 (section), the bulb dilates every part of the vagina and its fornices, according as it is manipulated and levered while the fluid distributes itself just as widely, practically, as it would when passing through a number of perforations This simply-constructed bulbous tube in glass or vulcanite is thus the easiest possible to keep clean, it may be antisepticised more readily and perfectly than any other vaginal tube in existence. In the case of glass the bulb is not solid between the bore and the circumference, but hollow as seen in Fig 2 (section), and there is no communication between the bore and the cavity of the bulb Experiment shows that a tube having a solid walled bulb could not be made in either glass or earthenware, and if it could be made it would not lend itself for fine manipulation as does a hollow lighter one. The glass bulb illustrated also floats in fluid and may be dropped into a vessel containing fluid without breaking

FIG. 1.

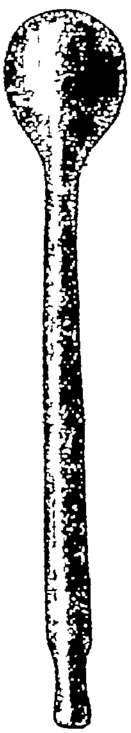

FIG 2.

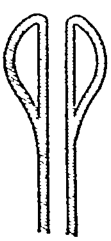

Section.

FIG 3.

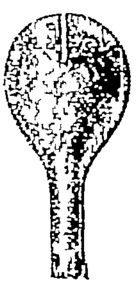

FIG 4

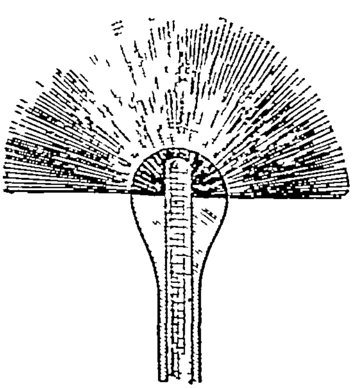

Section.

Another vulcanite form of tube, Fig 3 and Fig 4 (section) has its single bore met near the end by a very narrow bisecting slot, which not only spreads the fluid, as seen in Fig 4, but prevents the tube from being blocked by clot or other material returning in a back flow, as the perforations of tubes commonly used frequently are. This form of tube may be preferred by those who use a Higginson's syringe. The small end of each tube is made to fit any ordinary indiarubber douche or syringe tubing

The glass tubes are made in one design, as illustrated in Fig 2, and with one size of bulb only, namely one and a quarter inches in diameter In vulcanite the bulbs are of two sizes, one and three-eighths and one and one-eighth inches respectively in diameter, and have two distinct designs the one having a single bore and the other a single bore met by a slot. They are supplied by W H. Bailey and Son, 38, Oxford street, London, W

Surbiton. HAYDN BROWN

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A COMITIA was held on Feb 19th, Sir WILLIAM SELBY CHURCH, Bart., K C B, the President, being in the chair The meeting had been adjourned from Jan. 29th.

A report was received from the Laboratories Committee, dated Dec 5th, 1902. On the motion of the Senior Censor (Sir R. DOUGLAS POWELL), seconded by the Second Censor (Dr G VIVIAN POORE) the report was received and adopted.

The Harveian librarian (Dr J F Payne) presented a list of books and other publications which had been given to the library during the past quarter and the thanks of the College were ordered to be given to the donors.

The annual return by the examiners of the results of the examination for the Licence in the year 1902 was received and ordered to be entered on the minutes.

The PRESIDENT then dissolved the Comitia.

ANNUAL DINNER OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The members and friends of the West London Medico-Chirurgical Society held the twenty-first annual dinner of the society at the Trocadéro Restaurant, London, on Feb 19th, under the chairmanship of the President of the society, Mr Rickard W Lloyd. The first toast after the customary loyal toasts was The Imperial Forces," proposed by Mr T R. Atkinson who in the course of his remarks on the medical department of the army pointed out that the institution of the Medical Staff College in the metropolis was a great sign of the times. Sir William Taylor, K.C B (Director General of the Army Medical Service), in reply referred to the services rendered by the West London Medico-Chirurgical Society and similar associations in the cause of the wives and children of those who were obliged to go on active service He looked forward to the time when the civil members of the medical profession would know more of the medical department of the army and he trusted that the establishment of the Medical Staff College in London would prove that its members were not unworthy of the consideration of their brethren. The toast of the "West London Medico-Chirurgical Society" was given by Mr F Swinford Edwards and acknowledged by the President Mr C R B Keetley followed with a witty speech in which he proposed "The Kindred Societies." Mr Howard Marsh, who replied in his official capacity as the President of the Clinical Society of London, received hearty applause for a spirited and humorous answer to Mr Keetley's good natured raillery Dr Seymour Taylor proposed 'The Guests," for whom Dr J F W Silk answered After Mr Lloyd had acknowledged the toast of 'The President," proposed by Dr F F Schacht, the officers of the society, Mr T Gunton Alderton (treasurer), Dr E. A. Saunders (senior secretary) Mr H. P Dunn (editor of the society's journal), and Mr W McAdam Eccles (editorial secretary), duly acknowledged the compliment paid to them by Mr Alban H. G Doran.

had been intimately associated with Paget for 50 years. Sir Thomas Smith seems to have been most impressed by Paget's enormous capacity for work. "It was with him a recreation, or rather a passion." "In his own work Paget certainly showed a complete disregard of his health and personal comfort." When quite an old man, however, he seems to have realised that a man can overwork, for he said to the writer of the postscript, "I have worked too hard, Tom." The increasing infirmities of age are irksome to everyone and must have been doubly so to one so active as Paget, but these memoirs and letters so carefully and lovingly edited by "one of his sons" show, again to quote Sir Thomas Smith, "how contentedly he acquiesced in the necessary restrictions of increasing infirmity and with what cheerful submission he resigned his life."

A Concise History of the North Staffordshire Infirmary and Eye Hospital. By RALPH HORDLEY. Newcastle-under-Lyme: G. T. Bagguley. 1902. Pp. 71. Price 5*s.* net.—In 1902 occurred the centenary of the foundation of the North Staffordshire Infirmary and the year was further marked by the laying of the foundation stone of the new nurses' home, a building erected in memory of the King's Coronation. In honour of these two events Mr. Hordley, who was formerly secretary and house steward, compiled this concise history. The institution started as the Dispensary and House of Recovery in Etruria Vale and was erected on a plot of land purchased from Josiah Wedgwood in 1802. Here it remained until 1815, when it was moved to Etruria and was called the North Staffordshire Infirmary. In 1869 another move was made to Hartshill when it was called by the additional title of Eye Hospital. Mr. Hordley's researches into the archives of the institution show the steady progress made in the buildings and in the methods of treatment in vogue. We may add that the last addition—namely, the nurses' home—has cost £10,000.

Bacteria in Daily Life. By Mrs. PERCY FRANKLAND. London: Longmans, Green, and Co. 1903. Pp. 216. Price 5*s.* net.—This is a popularly written but none the less accurate account of the influence of bacteria in everyday matters. Much of the text, we learn from the preface, has already appeared in various periodicals, but a great deal of the book is worth spreading broadcast, not only from a medical point of view but also from those of social and political economy. Thus the chapters on What we Breathe and on Sunshine and Life may well induce county councils and other authorities to do everything in their power to inhibit overcrowding and the smoke nuisance, while the chapter on Milk Dangers and Remedies shows very clearly how the prevailing agricultural depression might be largely lessened if our farmers and landowners would only follow the example of Denmark and see about organising dairy produce in a scientific and cleanly manner. In the year 1898 this country imported in round numbers 360,000,000 pounds of butter, and of this quantity Denmark alone sent to us over 160,000,000 pounds. The last chapter of the book, entitled "Some Poisons and their Prevention," deals with the question of antitoxins and immunity, and though wisely not going deeply into the very difficult subject of immunity, Mrs. Frankland has collected a number of facts from the work of investigators which will give the ordinarily intelligent reader a good idea of the work accomplished in this field of science up to the present time.

The People of Lewis. Report to the Secretary for Scotland by the Crofters' Commission on the Social Condition of the people of Lewis in 1901 as compared with 20 years ago. London: Eyre and Spottiswoode. 1902. Pp. 65—civ. Price 1*s.* 5*d.*—An interesting Blue-book has recently been published on the social condition of the people of Lewis, a large island in the Outer Hebrides. The information contained in the volume is by no means confined to the strict letter of the title, for a good deal is to be found concerning the past history of the islanders. The report was drawn up to give an idea as to the best method of treating the problems conveniently summed up in the expression "the crofter question." The conditions of life which existed in Lewis some years ago were of the most insanitary nature as judged by modern standards; animals and men dwelt not only under the same roof but in the same room and the droppings of the cattle were removed but once a year when the land was tilled in the spring. A form of disease called "dung fever" was usually prevalent at that time of year and not infrequently proved fatal. Another disorder which was not uncommon in old days was one which afflicted young children about the fifth day after their birth. The disorder was investigated some years ago by Dr. C. M. Macrae ("On Tetanus Nascentium.") Notwithstanding these and other drawbacks the birth-rate is very high and the population is increasing rapidly. For a long time this has been a cause of uneasiness to the lords of the soil, one of whom, in the early part of last century, "used every means in his power to keep the population down." This singular statement occurs in the evidence given at an inquiry held in 1827. The land available for crofters has been insufficient for their wants, and in course of time it has happened that those who have had holdings have allowed their families to share their rights with them and new buildings have been put up for the accommodation of the younger people, the amount of land under tillage not being increased. One of the problems on which the Commission has had to report is what in these circumstances should be done. Another point which the Commission investigated had reference to an alleged increase in lunacy amongst the islanders. The result of this inquiry seems to make it clear that the chief change has taken place in regard not to the numbers but to the treatment of lunatics. Formerly they were not interfered with and lived as they chose; at the present time they soon come under observation and are removed to the asylums provided for them. The people of Lewis are a very fine, a most prolific, and a most industrious race. The men take more than their share in national defence. In the Royal Naval Reserve alone the Lewis islanders had over 2000 men in training during last year. The home industries of Lewis are few, but a considerable amount of cloth is still made as well as a little pottery. The pots, which are only manufactured at one place, are rude and primitive in appearance and are little used for home purposes, but it is pleasing to know that considerable quantities of them are sold in the course of a season to the "curio-hunters" for whom they are designed.

The Truth and Error of Christian Science. By M. CARTA STURGE (Moral Science Tripos, Cambridge), with introduction by Rev. H. S. HOLLAND, Canon of St. Paul's. London: John Murray. 1903. Pp. 160. Price 6*s.*—Miss Sturge has so thoroughly exposed the true nature of that conglomeration of mistake, conviction, and blind assertion which goes by the name of Christian Science that her work is perfectly intolerable. To say this is to pay her the truest compliment. No sane mind can tolerate page after page of such mistaken logic and such crooked conviction as are revealed in the works of the "founder" of Christian Science; and in the same way Miss Sturge has so conscientiously expounded and demonstrated this new doctrine that her work, through its very excellence, produces a degree of mental irritation that makes the complete perusal a sheer impossibility. Miss Sturge deserves great credit for the sober and quiet way in which she has sought to understand the sensational statements, the unwarranted conclusions, and the untrustworthy premisses of Mrs. Eddy, and still more for the judicious and impartial manner in which she, so to speak, shows up Christian Science as a mistaken philosophy, if philosophy it can be called at introduction of acid water arise, and the efficiency of the method of meeting these risks should be constantly checked and wherever possible improved upon. When the matter is dealt with on proper lines there is, in Mr POWER'S words, "no difficulty whatever in safeguarding a population supplied wholly or partly from moorland sources from risk of receiving water capable of dissolving lead." A detailed account of the nature of the precautions which should be taken will be found in Dr HOUSTON'S report, and his description of the tests for acidity and "plumbo-solvent" ability, which he has adopted after a long series of comparative experiments, should be particularly useful to those concerned. We are glad to notice that Mr POWER speaks apologetically of the use of the term "plumbo-solvent" It does no credit to the English language and we think if a new term was necessary some more euphonious and accurate word might have been coined

◆

Adenoma of the Rectum

THE Erasmus Wilson lectures at the Royal College of Surgeons of England were delivered this year by Sir CHARLES B BALL, Regius Professor of Surgery in the University of Dublin. He took as his subject adenoma and adeno-carcinoma of the rectum The choice was a very happy one as it is a subject which has hardly been studied with the attention which it deserves We are quite ignorant of the etiology of adenoma of the rectum and we have not yet determined the relation between the simple benign adenoma and the adeno-carcinoma of the rectum which is the commonest malignant growth of this portion of the alimentary canal. The lectures were very copiously illustrated by lantern slides which showed clearly the macroscopic and microscopic characters of the growths From a very early period in the history of medicine the diseases of the rectum attracted much attention on the part of physicians, for the rectum is the only portion of the bowel which can be examined during life without cœliotomy, and therefore, at a time when necropsies were hardly ever performed, the rectum was the only portion the diseases of which were the subjects of accurate knowledge. It is, therefore, with interest that we turn to the fathers of medicine to see if they have written anything about so striking a condition as adenoma of the rectum. We find that among the works which are attributable to HIPPOCRATES or are the products of his immediate successors is a small treatise on hæmorrhoids This contains a reference to a condition called the "bleeding condyloma of the rectum." It is not improbable that this term includes other forms of growth, such as venereal warts, but it can hardly be doubted from the description and the treatment that it was applied especially to the sessile or pedunculated adenoma of the rectum CELSUS also gives a similar account and all subsequent writers on surgery up to modern times have treated of this pathological condition.

Sir CHARLES BALL pointed out that it is very difficult to draw any sharp line between the benign adenoma and the malignant adeno-carcinoma and said that the only test which our present knowledge affords us is the relation of the epithelial proliferation to the basement membrane So long as this proliferation is simply a superficial development, even though it may produce a definite tumour projecting into the lumen of the bowel, we may look upon it as benign, but if, on the other hand, the proliferating epithelium pierces the basement membrane and invades the submucous layer and the muscular coat, or involves the tissues external to the bowel wall, then we are compelled to regard the growth as malignant, for it manifests all the clinical characters of malignancy In some cases on digital examination the diagnosis between these forms of growth can be made with confidence, the superficial character, the softness, and the mobility of the simple adenoma being obvious, while in the case of the malignant growth its hardness and fixation proclaim at once its malignancy In other instances, however, the assistance of the microscope has to be invoked before any certain diagnosis can be made Hæmorrhoids are confined to the rectum, but these adenomata, both the simple and the malignant forms, are found throughout the entire length of the intestinal tract, though they are much more frequently met with in the rectum The lecturer was inclined to attribute to local irritation the origin of some of the simple adenomata, for he pointed out that in cases of prolapsus recti in young children it is not rare to find small sessile adenomata on the exposed mucous membrane—too small, indeed, to have assisted in the production of the prolapse, but possibly produced by friction against the child's clothes. Upon the exposed mucous membrane of a colostomy, also, similar growths may be seen to appear Sir CHARLES BALL objects on etymological grounds to the use of the word "polypus" for the pedunculated variety of the adenoma and, indeed, its use cannot be defended. The treatment of the benign adenoma is simple, for the more pedunculated forms ligature with removal by scissors is all that is required, while the more sessile varieties may be excised. Sir CHARLES BALL in his second lecture dealt with the "adeno-carcinoma," and showed that there are two distinct clinical types, one commences as a flat nodule in the mucous and submucous tissues, spreading somewhat rapidly and occurring more commonly in comparatively young subjects, the other is more superficial at first, does not grow so rapidly and contains more fibrous tissue, by the contraction of which stenosis of the bowel may be produced leading to intestinal obstruction. The histology and the symptoms were detailed, and much emphasis was laid on the urgent necessity for the early local examination of all cases of chronic diarrhœa, seeing that on an early diagnosis depends the hope of satisfactory treatment of the disease. For when the lymphatic glands are involved and the malignant growth has extended beyond the bowel wall there is but little reasonable expectation of extirpating the tumour

The lectures were excellent and were founded on a vast clinical experience and will doubtless appear in book form, when we hope that a few points which demand further investigation will receive the author's consideration. Sir CHARLES BALL agrees with most histologists in looking on these simple rectal growths as true adenomata and the question arises, are they really adenomata? He has pointed out himself in his first lecture the very close analogy which exists between these "adenomata" of the intestinal mucous membrane and cutaneous warts. Now the chief reason for considering these adenomata to be glandular in structure is that on

THE LANCET.

LONDON SATURDAY, FEBRUARY 28, 1903

Moorland Waters and Lead Poisoning

A REPORT has just been issued by the Medical Department of the Local Government Board which gives details of a prolonged research undertaken by Dr A. C HOUSTON on the power which certain moorland waters possess of dissolving lead The object of the research was to determine the causes of the acquisition by water of this "plumbo-solvent" ability and to ascertain the extent to which the large moorland gathering grounds of Lancashire and Yorkshire are liable to furnish water capable of exercising the objectionable property of acting upon domestic lead service pipes So far as the cause of the phenomenon is concerned, Dr HOUSTON'S completed records point to conclusions which are substantially the same as those which the present medical officer of the Local Government Board, Mr W H. POWER, C B, drew tentatively in 1895 as a result of his own earlier inquiries into lead poisoning in Sheffield and of study of the data subsequently obtained in his department

Briefly stated, a water which is capable of dissolving lead is acid and its acidity is ultimately to be referred to drainage from peaty soil. The formation of acid takes place within the peat itself and results from the action of specific bacteria, which, when isolated, possess the power of rendering by their growth a sterile neutral decoction made solely from peat both acid and possessed of "plumbo-solvency" The degree of acidity of a given supply is determined by the presence of peat on the gathering area and by the conditions under which the drainage of the peat gains access to the supply The degree of its "plumbo-solvent" ability, broadly speaking, corresponds to the degree of its acidity, although the ratio is not necessarily quite the same for all peaty waters. The natural conditions which favour the access of peaty water to a supply are, of course, numerous and varied. The most dangerous period is commonly when a sharp storm succeeds a long period of drought, the "first washings" of peat in these circumstances being particularly acid. Hence, as Dr HOUSTON shows, there is much advantage in placing "leaping weirs" across the tributary streams concerned, arrangements designed to exclude these first washings automatically from the supply Whether the water derived from peat which ultimately reaches the waterworks reservoir is acid or not depends to some extent upon the distance traversed and upon the character of the bed of the stream, but is mainly determined by the extent to which it becomes mixed with spring water, which (at any rate in the Lancashire and Yorkshire districts) seems habitually to possess acid-neutralising properties. Out of 58 reservoirs served by the gathering grounds of 23 waterworks visited by Dr HOUSTON no less than 35 contained acid water able to dissolve lead. Among these are reservoirs of such important municipal supplies as Bradford, Halifax, Keighley, and Oldham In most instances the source of acidity could be traced to particular peaty streams and their small tributaries The occasional ingress of large volumes of acid water in times of storm by way of these feeding streams, and in part the fact that the bed of the reservoir is frequently itself peaty, account for the circumstance that the water of storage reservoirs was in some instances found to possess an almost constant degree of acidity year after year

Fortunately acid water from such reservoirs is seldom supplied directly to the consumer Most large waterworks in Lancashire and Yorkshire have service reservoirs which receive their water from more than one source of storage, and Dr HOUSTON gives many instances where, under normal conditions, admixture with a large volume of neutral water in itself suffices to render the mixed water harmless as regards lead. Moreover, the ordinary process of sand filtration exercises a considerable effect in counteracting acidity In several instances it is customary to add lime or whiting at the waterworks as a matter of routine, and this, when properly done, prevents the water from acting on lead. The practical question, however, is whether the precautions taken are uniformly efficient Wholesale poisoning such as occurred in Sheffield in 1886 and in Mossley in 1893 is comparatively rare But there have been several recent occasions in other Yorkshire and Lancashire towns where prevalence of lead poisoning has occurred to a minor extent And, as Mr POWER points out in his introduction to Dr HOUSTON'S report, "it is important to remember that if owing to temporary omission of precaution a water supply becomes possessed of plumbo-solvent properties for only a brief period, or if again a water habitually exercises only a slight solvent action on lead, it is likely that the number of cases of lead poisoning occurring at a given time will be small and that few will come under the notice of any one medical observer It is easy to understand that in such instances mischief may be caused unknown to the responsible authorities, or that even if mischief is suspected, the matter may receive insufficient attention through failure to realise that in such circumstances the evidence that the poisoning is attributable to the water must of necessity be incomplete" The warning here given will be indorsed by medical officers of health who have had occasion to be suspicious of the occurrence in their districts of lead poisoning due to water, and it should not be forgotten by waterworks engineers It is unfortunately too common for the "waterworks department" of a large municipality to discourage advice from experts of other departments and the danger of this policy is obvious where any question of lead poisoning is likely to arise. All assistance which medical officers of health can give should be welcomed and the borough analyst, as the official chemist, should be used, not merely, as at present, to give an occasional assurance that a particular sample of tap water contains no lead, but also to examine systematically and frequently representative samples taken at different points in the distributing area and from the reservoirs and filters In other words, every authority supplying moorland water should know precisely where the risks of the

There is yet another uncertain element in an examination and that is luck. Of course, in a theoretically perfect examination luck should have no place, but practically it often influences the result A question may be put which bears on a case recently seen or a chapter recently read and so success may follow, while if a similar question on another part of the subject had been given failure would have resulted. Yet the fact remains that a well read man who knows his practical work ought to be able to pass the examination even though he may not have found in his books the answers to all the questions exactly in the words in which he must express them. There is one danger in reading which needs to be guarded against and that is the tendency to dip into too many books. One work mastered is of far greater value than two half learned. Let the student, therefore, choose his text-book with care and then proceed to master it. When that book is finished he may, if time permit, peruse another and he will derive benefit from seeing the same facts presented in a different way

◆

The Sale of Poisons

THE report of the Departmental Committee appointed by the Lord President of the Council "to consider Schedule A to the Pharmacy Act, 1868, and to report the alterations therein which it deemed expedient and whether a third part should be added thereto," was issued last week For some time past the rumour had gained currency that the committee had decided upon the adoption of a third part in the schedule which would concede some relaxation in regard to the sale of poisonous materials for agricultural and horticultural purposes. As a matter of fact, the committee has decided that such a part might be added without undue risk to human life. On the face of it this recommendation is of course directly opposed to the vital principle of the Pharmacy Act which practically placed the sale of poisons exclusively in the hands of qualified persons—that is to say, pharmacists who have been duly registered in accordance with the provisions of the Act. The vendor of preparations for use in connexion with agriculture, horticulture, or sanitation is not, according to the recommendations of the committee, to be a qualified man but only a licensee, the sale of such preparations being subject to regulations to be laid down by the Privy Council.

There can be no doubt that some inconvenience has been experienced by the agricultural and horticultural industries in obtaining what are powerful aids to those businesses—namely, arsenical sheep dips and weed destroyers. As a matter of fact, large quantities of these preparations have been sold illegally and in contravention of the requirements of the Pharmacy Act, so that the Pharmaceutical Society has not been able to exercise fully the powers conferred upon it with a view to restrict the sale of poisons to registered persons Now and then, however, action has been taken and convictions have been obtained We have recorded in the columns of THE LANCET instances in which the proceedings were based upon the sale by seedsmen or florists of a weed killer containing arsenic. Since these convictions were obtained some uneasiness has been felt amongst the retailers of this class of poisonous preparation, many of them hesitating to continue the sale for fear of the law being carried into effect in their cases also So far the Pharmaceutical Society had scored some sort of a triumph and it cannot be said that it was exceeding its duties in this matter in the least degree or was pursuing a vexatious line of action. It possessed full powers under the Pharmacy Act to restrict the sale of poisons even for the specific purpose indicated. The success of these actions, however, was the beginning of a strong movement amongst the agricultural and horticultural interests to secure the removal of the restrictions under which they laboured, with the result that a departmental committee was appointed and its conclusion now is that certain concessions should be made It is of opinion that preparations for use in connexion with agriculture, horticulture, or sanitation (including arsenic, the alkaloids of tobacco, and carbolic acid) might be placed in a third part of the schedule, and that they should be sold only by licensed persons and be subject to regulations to be made by the Privy Council.

Although it seems to us that this recommendation suggests a somewhat hazardous experiment, it must be admitted that the arguments in favour of such recommendations being adopted are not without force It should be remembered that the Pharmacy Act was drawn up in 1868, at a time, that is, when there could not have been the slightest idea that this Act would ultimately apply to industries dependent upon the use of poisonous materials. No one can contend for a moment that the sale of a weed killer or insecticide requires the supervision of a particularly well educated or qualified person such as is the registered pharmacist. But it is to be hoped that in the event of the committee's recommendations being adopted at least an intelligent person will be chosen. The Pharmacy Act in reality appointed the registered pharmacist to be the qualified vendor of poisons intended for medical application, because obviously only a responsible person with an accurate knowledge of poisons should be trusted to sell or to dispense preparations containing them The employment of poisons for agricultural purposes cannot be said to relate in any way to the business of a pharmacy Whilst, however, we are inclined to agree with the committee that the industries of agriculture and horticulture cannot be conducted effectively on modern principles without the extensive use of poisonous materials we are by no means certain that the relaxations suggested can be conceded without, as the committee puts it, undue risk to human life. At the same time, we are not sure that, if every hamlet and village could have its qualified pharmacist who would be authorised to sell poisonous materials, the public interest would be more effectually safeguarded. The risk, it seems to us, begins after the sale is effected and when the article is in the hands of the purchaser The committee practically adopts the view that if the number of registered pharmacists were increased—that is, if every little place in the United Kingdom could have its pharmacy—there would be no necessity to extend the sale of poisons to licensed persons or to persons who are not registered as pharmacists One complaint of the farmer and gardener is that there are not enough pharmacists in the United Kingdom to distribute the poisonous materials which they require. Therefore the committee suggests that an ironmonger or a microscopic examination tubular cavities can be seen lined by a modified columnar epithelium, resembling somewhat the Lieberkühn follicles of the bowel. In a section of an ordinary papilloma of the skin an exactly similar structure is visible. The digitate processes of the wart give rise to cleft-like spaces between them lined by the epithelium of the part, and therefore we would suggest that the so called adenoma of the rectum is simply a papilloma growing from the rectal mucous membrane and that the so-called glandular spaces are merely the fissures between the papillary processes In the more marked "villous" adenomata this structure is obvious and it is extremely probable that in the conglomerate forms the same structure obtains. The rectal adenomata also resemble the cutaneous papillomata in the frequency of their occurrence in the young, and in both forms the removal of a single growth may be followed by the appearance of a large number of similar tumours This is not rarely observed with warts and a few cases have been recorded in which a similar result occurred on the removal of a single rectal adenoma Mr THOMAS BRYANT published in THE LANCET in 1898[1] a very striking case in which after the removal of one "polypus" the rectal mucous membrane ultimately became almost covered with sessile outgrowths There is yet another similarity between rectal adenomata and cutaneous warts. They are both very liable after existing for years without apparent change to spread into the deeper tissues and to become carcinomatous. We suggest that the "adenoma" of the rectum may be truly a "papilloma"

The Choice of Books

THE selection of a text-book by the student of medicine is often extremely difficult, yet on a judicious choice of works for his reading depends much of his success at examinations. That this difficulty in choosing is felt by many is clearly manifested by the frequency with which we are asked to advise on a course of reading for some examination. We always answer these correspondents to the best of our knowledge, but we often find it impossible to name an individual book which will fulfil exactly the requirements In the Students' Number of THE LANCET we give every year lists of those works which we consider to be on the whole the most suitable for students. It must, however, be acknowledged that whatever care be devoted to the making of such a selection the result will not be always perfectly satisfactory in the case of every student There is no work on any subject which is suitable for all candidates and for all examinations Even when there are two books of equal standing it may be almost impossible to say which is the more suitable of the two To take an instance a few years ago the two chief text-books on physiology in the English language were FOSTER'S Physiology and LANDOIS'S work as translated and edited by STIRLING No one conversant with the subject would deny that each of these treatises was a work of the highest class and that either could be studied with great benefit by a candidate for any of the higher examinations in physiology, yet it would be difficult to imagine two books more different in style and structure. The treatise of LANDOIS and STIRLING is a vast storehouse of facts in which the reader finds all the information which he could possibly require in an examination, but the very presence of so many data is in itself liable to confuse the mind. In FOSTER'S Physiology, on the other hand, a wide view is taken of the whole subject and the trend of research is clearly shown, but there is a total disregard of the individual unconnected fact, which is sometimes trying to a student searching for specific information. We have chosen this example to show that in many cases no single text-book, however perfect it may be, is necessarily sufficient for a particular examination.

The proper foundation for a student's knowledge should be laid in his lectures and his practical work. In some cases the lectures may entirely obviate the necessity for any text-book and we have known a candidate to obtain the gold medal in medicine at the M B examination of the University of London who had never read any work on medicine other than the notes of his lectures. Of course, this was an exceptional case, but as a student has to be "signed up" for attendance at lectures he should derive as much benefit as possible from them. To the practical work especially should he pay attention, for the knowledge learnt by practice is much more easily retained than is that learnt only from a book Still, in nearly all cases a treatise on the subject in which the candidate is to be examined needs to be read In the first place examinations differ greatly among themselves. Even when two examinations are of about the same degree of difficulty it does not necessarily follow that the same text-book will suit both. The experienced teacher will know and recognise how true this is. Candidates, moreover, vary greatly, not merely in mental capacity but also in the build of mind, so that for no definite reason a work that is easily read by one student is wearisome and distasteful to another The mode of presentation of the facts and theories of a subject may be to the liking of one candidate, while to another it may prove utterly unsympathetic. There is also such a condition as mental dyspepsia. In the case of food, it is not merely necessary that an article of diet should contain a large amount of proteid or fat to render it suitable as food but that it should also be readily digested and absorbed, so is it with mental diet. If the information in a work is so concentrated that it cannot be digested and absorbed into the mind of the reader it cannot nourish him mentally but will serve only to irritate

We have said that examinations and candidates differ, examiners differ also Some men are born examiners, they can ascertain both in *viva voce* and in written examinations exactly what the candidate knows, they are reasonable in their requirements and considerate in their manner and the result of the examination may be trusted as correct. Others, with the best intentions in the world, never make good examiners. The questions which they set are obscure in meaning and the candidate in addition to his ordinary anxiety about the examination fears that he has misinterpreted the question, or the student is expected to know some rare fact of which probably he has never heard. Some examiners put questions which can be answered word for word from a text-book, others ask for information which may require extensive synthetic mental processes temper, and energy in the performance of their almost parental duties, then the results should be very good.

THE ROYAL DENTAL HOSPITAL AND ITS ANÆSTHETISTS

WE are very glad to learn that the summary dismissal of the anæsthetists of the Royal Dental Hospital from their appointments is not to take place Our readers are familiar with the situation which was recently set out in our columns.[1] At a meeting of past and present anæsthetists of the hospital on Feb 10th the following motion was unanimously carried —

> That this meeting whilst fully endorsing the protest recently made by the staff of anæsthetists to the managing committee, desires to express to the committee the opinion that by the radical change in the anæsthetics department which is proposed no small degree of responsibility will be incurred, and that such a departure from a time-honoured system as that contemplated is not only opposed to the interests of the hospital but to the safety of the patients treated within its walls.

The resolution was considered by the managing committee of the hospital at its meeting on Feb 19th, when it was resolved —

> That the changes recommended in the report of the sub-committee appointed Nov 16th, 1902, and adopted by this committee on Dec. 18th, 1902, be deferred.
>
> That with the object of having the question reconsidered the anæsthetists be asked to submit to the managing committee a scheme for the efficient working of the anæsthetic department of the hospital.

The managing committee in communicating this resolution to the anæsthetists has expressed its assurance that the anæsthetists will willingly carry out the duties of the department during the interregnum. This we are sure that they will do, and we trust that they will also bring a business sense of what is really wanted to the drawing up of a plan for the proper working of their department. It is so usually taken as a sign of strength and wisdom not to change a declared intention that we congratulate the managing committee upon not being afraid to wait and to reconsider its startling decisions. We hope that it will find itself able to adopt, at least in essentials, the scheme to be submitted to it by the anæsthetists

A FORGOTTEN EMBRYOLOGIST

PROBABLY few of the readers of THE LANCET have heard of the embryologist, Sébastian Graf von Tredern, the romance of whose life and work forms the subject of a brief feuilleton in the *Wiener Medicinische Wochenschrift* of Feb 14th. Born in France, at Brest in 1780 and exiled to Russia in his fifteenth year, he became an officer in the Russian navy, then studied medicine in Germany, at Würzburg and Göttingen, graduated as doctor of medicine at the University of Jena, and a little later returned to France to enter the navy as a surgeon, being sent to Gaudeloupe in the West Indies he founded a hospital there and died shortly afterwards in his thirty first or thirty second year, though the exact date of his death is unknown. His father, a member of an old Breton family, was a captain in the French navy but being exiled to Russia after the battle of Quiberon in 1795 and being kindly received by the Emperor Paul he entered his son Sebastian as a midshipman in the Russian navy While stationed at the harbour of Reval in Esthonia he began his noteworthy researches on the embryology of the chick, though it is unknown whether he had received any previous training in natural history The memory of the young officer who dissected animals, kept hens to brood over eggs, and who was moreover, a clever painter lived long in the minds of his contemporaries. He left the Russian navy in August, 1801, being then 21 years of age, and till October 1804 nothing is known of him, but on this date Sebastian Graf von Tredern of Livonia matriculated as a student of medicine at Würzburg While at Würzburg he worked with Döllinger and pursued his embryological researches with the utmost diligence. None of his contemporaries seem to have had the slightest suspicion of his French nationality, as he was regarded as a German from Livonia, and his amiable personality, good fellowship, and skill in the concoction of punch and similar beverages—no doubt the result of his naval experience—rendered him a universal favourite. In 1807 he repaired to Göttingen and discussed the publication of a large work on the development of the chick with Blumenbach who advised him to use a small part of his rich collection of material as a dissertation for his doctorate. This advice von Tredern acted upon and worked in Göttingen, here, again, according to the statements of some of his contemporaries, he was regarded as a German, his real nationality being concealed. Having prepared his dissertation he had it printed in Jena and was awarded his doctorate with distinction. In this work he announces his intention of carrying out a complete work on the subject, which intention unfortunately he did not carry out. In 1811 he passed the State examination at Paris and entered the French navy and shortly afterwards died at Gaudeloupe. With regard to the dissertation, it consists of only a few pages but has attached to it a splendid plate, the figures of which, though simple outlines, show a wonderful richness in detail, and the whole work indicates such great ability, such wide knowledge of the literature of the subject, and such capacity for research that the abandoning of the work and the early death of its author were undoubtedly a great loss to embryological science The reasons for his giving up research for practice and his return to France are unknown and are among the mysteries with which this strange history of a short life abounds

AMALGAMATION OF POOR-LAW UNIONS IN WESTMINSTER

THE Westminster city council has suggested that the three unions in that city should be amalgamated. The St. George's union contains a population of 128,000 the Westminster union has 33,000, and the Strand union has only 21,000 When the disparity in the sizes of these unions, the great number of separate official buildings, and the multiplication of staffs necessary for the carrying out of the work of the Poor law relief are taken into consideration, the fusing of the three appears to be a wise and economical procedure. The point, however, that more especially interests us in the proposal to amalgamate the three unions is the opportunity that would be afforded after the junction of initiating a much needed and often suggested reform—namely that of a better classification of the indoor poor Time after time has a demand been made for the separation of the infirm from the able-bodied and of the quiet and well behaved from the noisy and dissipated The public asks for a separation that shall be complete and that will allow an entirely different treatment of the two classes in the matters of comforts and privileges. Accommodation in adjoining rooms is not the separation that is required Hitherto it has been found impossible to effect a classification satisfactory in all respects in any one workhouse. Two difficulties are met with—the classes are too numerous for arrangement in one building, ages, sexes, and morals rendering them so, and the numbers in the various classes are ever changing Thus there might be at one period great overcrowding in a certain class and at another great waste of space owing to diminished numbers. The London unions at the present time own about 38 workhouses. It is futile to urge that in each of these there should be a classification of the inmates. If the workhouses themselves could be classified a solution of the problem would be in sight. Some of them might be set apart for the reception of the married couples, others might be devoted to the infirm and others to the aged but not infirm. It would then be possible to corn merchant might be licensed to sell these poisonous materials where a pharmacist does not exist for the purpose.

---

[1] THE LANCET Feb 14th 1903 p 453.

On the other hand, in a well and sensibly written minority report Mr WALTER HILLS maintains that the demand for the relaxation of the statutory restrictions emanates, not from agriculturists or from horticulturists, but from those persons whose natural desire is to promote the sale of their own particular preparations and he cites the remark of a witness who stated as a reason for objecting to the Pharmacy Act that he could not readily introduce poisonous novelties through pharmacists. He points out that this is distinctly a manufacturer's objection and is, in fact, the predominant note throughout the inquiry Some regard, he adds, must be given to the public side of the question and in his opinion it is an important advantage that pharmacists do act as a restraint upon the development of the retail business in poisonous novelties and do to that extent carry out the object which the legislature had in view in passing the Act. Mr HILLS, we think, was wrong if he thought that this admission could help his cause, for surely this statement supports the contention of the rest of the committee that the Pharmacy Act interferes with farmers and gardeners obtaining poisonous materials for a legitimate purpose conveniently and that the industries of agriculture and horticulture cannot be conducted *effectively* on modern principles without the *extensive* use of poisonous material (the italics are ours) We have misgivings as to the probable effect of the committee's recommendations should they be adopted in regard to the exemption of industrial poisons from the provisions of the Pharmacy Act. If the representatives of the trade are right in stating that there are not sufficient pharmacists in the country to meet their needs, cannot this deficiency be made good by appointing intelligent licensees, not universally throughout the country, but only in those thinly populated places in which it would not be profitable for a qualified druggist to pursue pharmacy as a profession? We strongly urge that the number of licensees should be strictly limited and that the privilege of selling industrial poisons should be extended only to those districts in which the druggist's shop is within decidedly less easy reach than the ironmonger's or other shops

As to the additions which it is recommended should be made to the poisons schedule the committee is in the main agreed The additions to Part I of Schedule A are cocaine and its salts, preparations containing 1 per cent. or more of morphine picrotoxin, and vermin killers containing poisons in Part I The additions to Part II. of the schedule are acetanilide and its preparations, preparations of cocaine, digitalis and its preparations, preparations of morphine containing less than 1 per cent, soluble salts of oxalic acid, mercuric iodide, mercuric sulpho-cyanide, strophanthus and its preparations, and sulphonal. It will be evident from two substances included in this list—viz., acetanilide and sulphonal—that many drugs used for the relief of pain and sleeplessness will have to be marked "poison." Finally, Mr ALEXANDER CROSS in a supplementary report makes the suggestion that power should be given to local authorities to grant licences to suitable persons to assist medical men in dispensing prescriptions when it becomes necessary to do so in the absence of the medical man, whether such persons have passed the Pharmaceutical Society examination or not. Our readers will agree with us in thinking that the suggestion is too ridiculous to be discussed. We can hardly believe that Mr CROSS is serious when he suggests that local authorities should have the power to grant licences to suitable persons for dispensing prescriptions. What do "local authorities" as a rule know about poisons? and how are they going to lay their hands on 'suitable persons"?

Annotations.

"Ne quid nimis.

COTTAGE HOMES FOR PAUPER CHILDREN

THE Hackney board of guardians has decided to spend about £50,000 upon the provision of cottage homes for the children of the union. The Plymouth guardians have adopted a similar method for the accommodation and education of their little ones In the latter case new structures are not to be erected for the purposes mentioned. Substantially built houses in good residential districts have been purchased These not being aggregated have received the name of "Scattered Homes." At Bath, at Sheffield, and at many other places separate buildings, each containing a small number of children, are now established Boards of guardians in different parts of the kingdom are moving in the same direction. Apparently at no distant date we may expect to see all the healthy "children of the parish" located in medium sized detached houses. The large district schools are out of favour They will probably soon be broken up into separate homes They have had a bad name given to them and the name has been as potent as the arguments in undermining their reputations. Yet the schools have done good work and they effected a vast improvement on the conditions that preceded them. So think many who have been intimately connected with their administration for long periods Be this as it may, cottage homes are now to be substituted They represent the embodiment of the latest suggestions for what has been called the depauperisation of the parish child They are being instituted in the fervent hope that the boys and the maids in due time may leave them with regret, taking with them no taint of pauperism, having healthy bodies and self reliant natures, possessed of knowledge of what a home really is and of the various duties that must be performed in every house in order to make it and to keep it a healthy and comfortable place of abode To this end the amount of education to be given by means of books will be just so much as is possible in the time afforded, but instruction in such matters as the preparation of the daily food, the making and the repairing of the clothing, and the arrangement and cleansing of every department of an ordinary dwelling will be imparted in an interesting and practical manner Will this new system be a continued success, or will a departmental committee after a few years swoop down upon it and urge its abolition with a report on its shortcomings? Time only can give the answer So far the system has certainly presented itself in a very favourable light, but we are convinced that it will stand or fall, not by reason of its perfection or imperfection, but by the merits and action of those upon whom the duty of carrying it out may be placed. By far the most important of these will be the matrons or 'mothers." Provided that the guardians exercise a wise discrimination in the selection of suitable persons to hold office as foster mothers and that these on their part exhibit skill, good of the population. The parents seldom or never pay any fee and the consequence is that the public vaccinator, who in rural districts is generally the local medical man, fills up the certificate for nothing as an act of charity It is no part of the duty of the medical profession to protect the Government from enlisting unfit employés, and, in our opinion, the Post Office should certainly pay for the certificate or else should send one of its regular medical officers to make the examination. But even where there is a local postal medical officer it would seem that it is at present no part of his duty to examine candidates for the post of telegraph messengers. Medical men take much time and trouble and spend large sums of money in fitting themselves for registration, but the benefits of registration are very small. The recently appointed Postmaster General might well see, we think, if he cannot do something to remove the grievance to which we have alluded

THE DISTRIBUTION OF PLAGUE

As regards Egypt the Director General of the Sanitary Department states that during the week ending Feb 15th neither cases of, nor deaths from, plague have occurred in Egypt The last case occurred at Tant-el Ghezireh on Feb 6th. As regards the Cape Colony the medical officer of health of the colony states that for the week ending Jan 31st 2 cases of plague were discovered at Port Elizabeth—namely, a native male who was admitted to the observation ward on Jan. 27th and who died from plague on the 29th, and a coloured male who was admitted to the plague hospital on Jan 31st and who died on the same date 1 case remained under treatment at the plague hospital, Port Elizabeth, at the end of the week. No case of plague has occurred at any other place in the colony

THE BRITISH GYNÆCOLOGICAL SOCIETY

A REVIEW of the history of the British Gynæcological Society formed the theme of the address delivered by the incoming President, Dr Heywood Smith, at the meeting of the society held on Feb 12th, an account of which will be found in THE LANCET of Feb 21st, p. 524 The life of the society is largely contemporaneous with the growth of gynæcology as a special branch of medicine, and in the account given by the President of the work done by the Fellows of the society the successive stages in the development of many of the operative procedures practised at the present day upon the pelvic organs can clearly be traced. If it were possible to assign to any one body of practitioners the credit for the popularisation and perfection of a special operative method, the Fellows of the British Gynæcological Society might well put forward such a claim with regard to the sub-peritoneal or intra peritoneal treatment of the stump in abdominal hysterectomy Indeed, Dr Heywood Smith was one of the first, if not the first, to practise this operation in this country, an advance in the method of treating the stump of the uterus of proved value. The Fellows of the Gynæcological Society have always considered the exhibition of specimens and the reading of clinical cases of the utmost importance, and have placed a higher value upon such contributions than upon the reading of set papers. Of the practical value of the meetings of the society the reports in the journal bear abundant testimony and the President may well say that it has done much for the advancement of the art of gynæcology The British Gynæcological Society dates its foundation from the year 1884 when it was started by a small band of workers, chief amongst whom were Dr Robert Barnes, Dr Alfred Meadows, and the present President. The society was an offshoot from the Obstetrical Society of London, and we, in common with many leaders of the medical profession, regarded the split at the time of its occurrence as distinctly regrettable This, however, is ancient history, and to-day the society is a successful and progressive one, possessing a good membership and a valuable quarterly journal. The abstracts of foreign literature which form one of the main features of the journal have been of great assistance to workers in gynæcology, and the society is to be congratulated upon the energetic band of workers who have devoted so much time to insuring the success of this part of the publication. The record of the meetings held up to the present date, some 234 in number, bears testimony to the vigour and energy of the Fellows and to the daily advance in the importance of the science and art of gynæcology An example of the growing specialisation of the work of the gynæcologist is shown by the fact that the council of the society has quite recently determined to institute an examination for the purpose of establishing a criterion by which the efficiency of nurses, especially those devoting themselves to gynæcological nursing, can be determined and to grant a certificate in monthly and gynæcological nursing to those candidates who are approved by the examiners. An important point is that no nurse will be allowed to enter for the examination unless she has had three years' training in a hospital. We are inclined to doubt the wisdom of this new step so far as monthly nurses are concerned Not only has the Obstetrical Society of London been carrying on for many years a similar examination, but the recent establishment of the Midwives Board appears to us to fulfil all the requirements of the case The Obstetrical Society, as soon as it is possible for it to do so, will no doubt hand over the conduct of its examinations to the new board and we do not see what advantages a certificate in monthly nursing granted by a private society like the British Gynæcological Society can have over a certificate granted by an official board instituted by Act of Parliament No doubt a certificate in gynæcological nursing will be found of advantage by nurses intending to devote themselves to that particular branch, and possibly such specialisation in nursing has some advantages. Since, however, it will be purely optional for any nurse to enter for the examination of the society or not, we fail to understand how it is "to prevent the market being flooded with so-called nurses who trade upon the public with inadequate qualifications."

THE PATHOLOGICAL ANATOMY OF SYPHILIS AND OF PARA-SYPHILITIC AFFECTIONS AS OFFERING A BASIS FOR TREATMENT

FOLLOWING upon the communication of Dr Leredde of Paris, to which reference was made in an *annotation in* THE LANCET of Feb 21st, p. 539, Professor J Renaut of Lyons contributes a paper on the subject of the pathological anatomy of syphilis and of para syphilitic affections to the *Philadelphia Medical Journal* of Jan. 17th. The gumma has hitherto been generally regarded by pathologists as the typical lesion of syphilis Professor Renaut shows that the reaction of the living tissues to the presence of the microbes of syphilis, glanders, and tuberculosis produces local changes of varying character The gumma is not the only neoplastic product arising from syphilis and moreover its structural character is variable according as it is one of the liver, the myocardium, or the brain, and all these gummata are different from those of the skin. A cerebral gumma is a nodule of which the periphery is constituted by proliferated neuroglia cells and fibres, the interior being a mass of degenerated brain substance the vessels of which have undergone obliterative endarteritis "Each tissue," adds Professor Renaut, "makes its gumma as it can.' The chief lesion of constitutional syphilis is arterial and even in the skin the rash of early secondary syphilis is the outcome of a paresis of the circular muscular fibres of the terminal arterioles of the bestow upon these broken down inmates more comforts, a greater freedom, and opportunities for interesting occupation To all these amenities the aged poor are admitted to be entitled, but there is little hope that they can ever obtain them so long as they share residences with the young, the able-bodied, and the badly behaved The new union will possess four workhouses and several other large buildings, such as schools or receiving houses Here then is a chance for the distribution of the poor upon an approved system—a system that would be much more kind but not more costly than the one which now obtains It is to be hoped that the guardians of the three unions will look upon the proposed scheme with favour To do so will, however, demand the exercise of a certain amount of magnanimity, for under the new conditions some of the guardians must necessarily cease to hold office.

PARATYPHOID FEVER

A DISEASE closely resembling typhoid fever and due to a similar and no doubt allied organism has of late attracted considerable attention from pathologists in France, Germany, and America. In the *Boston Medical and Surgical Journal* of Feb 5th Dr Joseph H. Pratt has published three cases of the disease and has reviewed its literature In certain typical cases of typhoid fever the Widal reaction is persistently absent. In 1897 Gwyn studied such a case in Osler's clinic at the Johns Hopkins Hospital. There were pyrexia, enlarged spleen, rose spots, delirium, diazo reaction, and intestinal hæmorrhage. From the blood a bacillus was obtained intermediate in type between the typhoid and colon bacilli. This bacillus belonged to a group which includes the bacilli of meat poisoning, the bacillus psittacosis, and the bacillus of hog cholera. Members of this group cause fermentation of glucose, thereby resembling the colon bacillus, but, like the typhoid bacillus, they do not form indol or produce gas in lactose media. In 1895 Gilbert gave the name "para colon" bacilli to this group and in 1896 Archard and Bensaude termed them "paratyphoid" bacilli The literature of the subject is already considerable. Two species of paratyphoid bacilli have been described by Schotmüller who terms them the "A" and "B" types. Both acidify milk, but the acidity produced by the "A" paratyphoid bacillus persists, while that produced by the "B" paratyphoid bacillus changes to alkalinity Archard and Bensaude reported the first two cases of "paratyphoid fever" in 1896. At present only 84 cases have been recorded; but the list is rapidly growing The following is an outline of Dr Pratt's cases In Case 1 a soldier who was invalided from Cuba while convalescent from typhoid fever complained of swelling of the right testicle. Incision was followed by the discharge of pus containing the "B" paratyphoid bacillus In Case 2 a girl, aged 18 years, was operated on for cholelithiasis The gall bladder contained four calculi of the size of chestnuts and apparently composed of pure cholesterin. From the centres of these the "B" paratyphoid bacillus was cultivated. In Case 3 a man, aged 38 years, had an illness characterised by abdominal pain and tenderness and pyrexia of two weeks' duration. During the third week left saphenous phlebitis developed. The blood serum agglutinated the "A" paratyphoid bacillus in high dilution and failed to agglutinate the "B" paratyphoid and the typhoid bacilli even in low dilution We may point out that of the conditions present in these three cases two—orchitis and phlebitis—are recognised complications of typhoid fever and that the other one—gall stones—has been shown by Gilbert and Fournier to be probably a result of typhoid infection of the gall bladder As to the pathology of paratyphoid fever, only four cases have been fatal and one of these was secondary to typhoid fever In the remaining three cases there were no intestinal ulcers and the Peyer's patches and solitary follicles were normal. But the fact that intestinal hæmorrhage occurred in five cases seems to show that intestinal lesions may occur In two fatal cases the paratyphoid bacillus was found in the blood taken from the heart, liver, lungs, and spleen. Perhaps some of the reported cases of typhoid fever without intestinal lesions are examples of paratyphoid fever Paratyphoid fever is usually a milder disease than typhoid fever and diarrhœa and termination by crisis appear to be more frequent. The duration has been from 12 to 84 days. Chills have occurred at the onset. Epistaxis has been observed in a number of cases First and second relapses have been observed. Rose spots and a palpable spleen were present in about half of the cases. The pulse was usually slow The urine frequently contained albumin. In uncomplicated cases there was no leucocytosis. The number and frequency of the complications are striking Bronchitis pneumonia, pleurisy, endocarditis, thrombosis, cerebral embolism, phlebitis, meningitis, peritonitis, cholecystitis, nephritis, cystitis, furuncles, osteomyelitis, myositis, and suppurative arthritis have been observed As to the diagnosis, our knowledge of paratyphoid fever is largely due to the practice of making blood cultures during life. This procedure has been shown to be a valuable means of early diagnosis of typhoid fever at a time when Widal's reaction is absent and the clinical phenomena are not characteristic [1] Similarly, the paratyphoid bacillus can be found early in the blood. In a number of cases the diagnosis has been made by cultivating the bacillus from the urine or fæces and showing that it was agglutinated by the patient's blood. If the bacillus cannot be cultivated from the blood, urine, fæces, or some lesion the diagnosis is justified if the blood agglutinates a paratyphoid bacillus in high dilution and fails to agglutinate the typhoid bacillus or agglutinates it only in very low dilution. The blood should be tested with both species of paratyphoid bacilli. A reaction with low dilution is valueless, as it may be obtained in typhoid fever and in other diseases.

THE MEDICAL PROFESSION AND MEDICAL CERTIFICATES

IT is a well known fact that no profession does so much for nothing as the medical profession. We are not referring to cases in which medical men give their services out of charity but to cases in which the Government or bodies such as the school board or friendly societies demand certificates for nothing We should say that by a convenient fiction it is not the school board that demands certificates but the magistrate For instance, all registered medical men are bound to give gratuitously a certificate of death, under a penalty of 40*s* if they refuse. The London School Board never pays for a certificate except when one has been taken exception to, and then it gives 2*s* 6*d* for confirmation of the certificate. The Post Office also, a Government department which earns some £4,000,000 for the revenue, practically places a quantity of gratuitous work on the shoulders of medical men. The regulations for the appointment of telegraph messengers state that "candidates will be required to produce a satisfactory certificate of health from their own medical attendant on a form to be provided for the purpose and a certificate of having been successfully vaccinated within the last seven years" Now what happens, in rural districts at any rate, is this The candidate applies to the public vaccinator for vaccination or revaccination and brings with him his form for a certificate of health to be signed by the public vaccinator The wages of a telegraph messenger are low—i e, 7*s* or 8*s* a week to commence with —and the candidates mostly come from the poorer stratum published in the *New York Medical Record* of Jan. 31st. He concludes that mental disease is not so frequently due to arterio-sclerosis as is commonly believed. Observations on the heart and aorta of the insane showed that arterio-sclerosis was exceedingly frequent, but mental disorder could be ascribed to such a morbid process only when it affected the blood vessels of the brain. In many cases of advanced chronic insanity or dementia such a condition undoubtedly existed. The progress of arterio-sclerosis in the brain was associated with loss of memory of the immediate past and attacks of mental confusion and transitory delirium. Such dements were found to be liable to indulge in petty larceny and sexual misconduct and they were frequently guilty of attempts to set fire to houses. Mental disease occurring in that period of life when arterio-sclerosis was most common showed, adds Dr Meyer, no peculiarity in its nature and course that could not be fairly accounted for by the commencing cerebral decadence of later life which was a prominent feature especially in neurotic subjects. Both senile and pre-senile decay of brain power was associated with arterio-sclerosis, but no special arterio-sclerotic insanity could be said to exist. When arterio-sclerosis was associated with insanity the prognosis was naturally more serious as there was no special treatment for such a diseased condition of the arteries of the brain.

[1] THE LANCET Feb 8th 1902, p 390

KING EDWARD'S HOSPITAL FUND FOR LONDON

THE annual meeting of the general council of King Edward's Hospital Fund for London was held at York House, St. James's, on Feb 24th, H.R.H. the Prince of Wales being in the chair The treasurer, Lord Rothschild, submitted the account of receipts and expenditure during the past year ending Dec. 31st, 1902. He mentioned especially the munificent gifts of Lord Strathcona and Lord Mount-Stephen Mr Edgar Speyer, and Mrs. Lewis. The receipts during the year had been £604,802 18*s* 5*d*, of which £28,729 12*s* 5*d* were annual subscriptions, £400,000 was the value of the capital given by Lord Strathcona and Lord Mount-Stephen, and the coronation gift was £118,663 13*s* 1*d* while the balance was made up by other donations and income from investments. £101,000 were distributed in gifts to the hospitals, made up as follows annual grants to 25 hospitals, £29,150, donations to 80 hospitals, £70,850, grants to 14 convalescent homes, £1000, which amount was received from the trustees of the London Parochial Charities. It may be interesting to mention the eight hospitals which have been allotted the largest grants, viz., London Hospital, annual £5000, donation £3500, Guy's Hospital, annual £5000, donation £2000, Royal London Ophthalmic Hospital annual £2000 donation £2500, University College Hospital, annual £1000, donation £2500, West London Hospital, annual £1500, donation £2000, King's College Hospital, annual £1000, donation £2000, Tottenham Hospital annual £1000, donation £2000, Metropolitan Hospital, annual £500 donation £2500 This accounts for £36,000 of the sum distributed. The working expenses amounted to £1942 2*s* 3*d* Of the balance of £501,860 16*s*. 2*d* £425 136 6*s* had been added to capital account (making it £447,225 15*s* 1*d*) and £76,724 10*s*. 2*d*. had been added to the general funds account (making it £229 583 6*s*) Thus the total amount of assets after deducting liabilities to sundry creditors, (£323 18*s* 5*d*) amounted to £676,809 1*s*. 1*d* to Dec. 31st, 1902, of which £662,000 were invested, producing an income of £24,000 a year The Prince of Wales, who was congratulated on the success of the Fund said that the King in his original letter in 1897 stated that their endeavour should be to raise an annual sum of from £100 000 to £150 000, but that to make up their income to £50,000 a year from investments an addition of £870,000 to the capital would be necessary The visiting committee had been largely increased. It was composed of 23 medical men and 23 laymen An important resolution had been passed requesting promoters of new hospitals or those reconstructing or extending within the area dealt with by the Fund to submit their proposals to the Fund, as it was felt that an independent authority like that Fund, possessing the willing and expert services of the highest representatives of the medical faculty, could render valuable assistance in such circumstances. The distribution committee was considering what steps could be taken to bring about the desired results in the amalgamation of certain hospitals and the removal of others to places where they were more needed The scope of the Fund would this year be extended so as to include the London County Council area, when outside the seven mile radius of Charing Cross, which would include new districts containing many poor and densely populated suburbs. The committee desired to point out that those who live outside London may reasonably be expected to give something to the hospitals of the capital of the Empire since 25 per cent. of the patients in London hospitals came from outside the metropolis The Lord Mayor (Sir Marcus Samuel) said that the preparation of accounts in a proper form was as good a work as the distribution of the money, and also that the time was coming when it would be necessary to stop instituting new foundations until those existing had adequate support Sir John Aird and Lord Rothschild having spoken the Prince of Wales in continuation said that they desired to express sincere gratitude to those who contributed small sums—shillings and pennies, and recognised that the results this year were exceptional and could not be looked for again. He assured his audience that His Majesty watched the growth and vitality of the Fund with as much interest and satisfaction as he did when he was President. The Prince concluded by saying that he was well aware of the heavy sacrifices of time involved by the labours of the council, committees, and officials, for which he offered them his grateful thanks and trusted that they would be kind enough to serve for another year in their respective capacities.

COAL SMOKE ABATEMENT

FROM some remarks which were made at the annual general meeting of the Coal Smoke Abatement Society held under the presidency of the Duke of Argyll at Grosvenor House on Feb 24th, it is clear that no country and no place where coal is used are free from the pernicious effects of smoke, but it does not follow that no attempt should be made to combat these effects. In this country public attention has often been called to the evils of coal smoke—its injuriousness to health, its destructive effects upon trees and flowers, its ruinous action upon pictures and furniture have all been noted. But until the advent of the Coal Smoke Abatement Society no organised effort was made to check the ills of which so many complain and which are so undoubted and so serious At the annual meeting of the society Sir William Richmond, R.A., the president, said that the delightful weather which we had been having for the last two months was in some measure due to the society and there is, we venture to think, a great deal of truth in this audacious statement. From Jan. 1st to Dec. 31st, 1902, the society's inspectors reported the result of 2470 observations which led to the detection of 1831 nuisances and 1701 complaints were forwarded to the corporation of the City of London, the London County Council, borough and district councils, and the port sanitary authority of London. In consequence of these complaints 88 summonses were issued and in 72 cases conviction was obtained with penalties and costs amounting to over £200 The total of the work done since the society was established in 1899 is as follows.

skin close to the surface. Thus are produced the areas or patches of cutaneous hyperæmia and redness which constitute the rash. A little amount of endarteritis is also produced, adds Professor Renaut, in these terminal arterioles of the skin but the lesion is slight and transient as regards the skin. In the later secondary stages of syphilis the endarteritis which may recur in the vessels of the skin, of the viscera, or of the nervous system is more marked. As a result ischæmia of the affected arterial territories follows and the tissues the nutrition of which depends upon the arteries suffer from defect of nutrition. The diseased arterioles become dilated irregularly and hyperæmia or even stasis of circulation results according to the character of the arterial change. Wherever it appears the special virus of syphilis produces subacute endarteritis obliterans, "causing chronic œdema and interstitial proliferation." At first diffuse and affecting vast arterial territories of the skin and body the morbid process limits itself later to special organs and viscera. Thus in tabes it affects the posterior spinal ganglia and columns, and in general paralysis the cerebral cortex and the central grey substance of the ponto-bulbar region. A comparison of the vascular and perivascular changes in syphilis proper and in the para-syphilitic affections, in the opinion of Professor Renaut, leaves little doubt that the two sets of changes are essentially not distinct one from the other They are, on the contrary, explained by him as depending upon the development of endarteritis, the differences being due to the extent to which endarteritis has advanced This progressive endarteritis, says Professor Renaut sets up an œdema and a sclerosis of the parenchymatous tissue "as the vasculitis progresses so does the sclerosis." In the central nervous system this sclerosis often affects "systems" of nerve cells and fibres as in tabes dorsalis (posterior root neurons) The central nervous system is generally attacked late—i.e , some years after syphilitic infection. And the vascular and interstitial changes produced in the brain by syphilis set up in turn a vicious circle of processes which continually interfere with the nutrition of the nerve cells and lead to their ultimate destruction. The successful treatment of the vascular changes, so as to arrest if not to abolish such changes, must hence, he is of opinion, be the basis for a rational therapy

THE OVEN AND THE SCREEN

IT is to be feared that many excellent modes of cooking which prevailed in the past are now abandoned simply to save trouble. The modern cook, or the person who calls herself such, although she may be positively instructed to roast meat in the good old fashioned way in a screen in front of the fire, commonly ignores her instructions at every possible opportunity and puts the joint in the oven. The introduction of the "kitchener" or the closed range and of the gas cooker probably accounts for the preference which is given to baking while it does away with the necessity of basting and other little but important culinary attentions which roasting involves. There can be little doubt that by this exchange of method not a few persons are dietetic sufferers. The preference for meat openly roasted before the fire is not a mere sentiment, for the flavour of meat so cooked is infinitely superior and the tissue is generally more tender than when it is baked. Now the flavour and tenderness of meat have much to do with its digestibility and consequently with its real value as a food. Without relish and appetite digestion is sluggish and heavy Indeed, it has been said that the process of digestion commences before ingestion and certainly the digestive functions are stimulated to healthy activity by the sight of a tender and well cooked morsel as well as by an excellent flavour or aroma. It has been shown that the mere inspection of good tempting foods starts the digestive machinery and immediately excites the flow of the gastric juice. It is, therefore, not unreasonable to suppose that there must be a difference of some dietetic importance produced in the organism when, on the one hand, a baked heavy looking joint is in contemplation and when, on the other, it is a bright attractive-looking, because an openly roasted, joint. Persons who have their meat from the same butcher naturally exchange opinions about the quality of the meat and it will often be found that when complaints are made chiefly in regard to the toughness and tastelessness of the joint the secret of it frequently is that baking is adopted instead of roasting As a matter of fact, there is a great difference between the two methods of cooking, baking and roasting In the former case the meat in reality is cooked in hot air which has a tendency to decompose the fat into acrid substances. When the door of an oven in which a joint is cooking is opened the fumes escape, smelling like a tallow candle which has just been blown out. The smell from a joint being roasted has not this character but, on the contrary, is agreeable In roasting the joint is cooked by radiation—that is, by the bombardment, so to speak, of heat waves. The air between the fire and the joint might be quite cool yet roasting would proceed all the same Roasting also is a less rapid method of cooking than is baking and slow cooking has very decided advantages in regard to preserving the nutritive value of the meat. The civilised cook might learn a good deal from the methods of slow cooking adopted by savage tribes. By one method, in which stones made hot with glowing charcoal are employed, a large joint, no matter how tough, may be exquisitely cooked and made tender and tasty and it is doubtful whether any form of so-called civilised cooking can compare with it. The navvy who fries his chop or steak on his spade over a few lighted sticks probably gets more nourishment and derives greater relish from the meat cooked in this way than if it had been baked in an oven.

AN EXPENSIVE FAD

"CONSCIENTIOUS" and other objectors to vaccination should read and digest the statement of the finance committee of the Metropolitan Asylums Board lately made upon the cost of the recent epidemic of small pox. It is conceivable that the pocket of the conscientious objector may be as sensitive in one direction as his conscience is in another and that the heavy drain which he, with other ratepayers, incurs through the epidemic which is fostered by non vaccination may influence his conduct in the future towards the rational measure of efficient vaccination and revaccination. Ordinary arguments and demonstrations do not appeal to the "crank" where his particular pet opinion is concerned, otherwise, of course, the demonstrated value of efficient vaccination would long since have been universally admitted. Half a million of money, however, spent from the rates upon a small pox epidemic constitutes a substantial argument even in the mind of an objector We recommend all those who do not approve of vaccination to descend from the heights of argument, where their prejudices render them unassailable, and to tackle the question on a purely material and pecuniary basis. Let them work out how much money would have been saved if all those upon the care of whom half a million pounds were spent had been protected from small pox by due attention to vaccination and revaccination at the expense of the ratepayer

ARTERIO-SCLEROSIS AND MENTAL DISEASE

THE important part played by arterial degeneration in determining cerebral disorders in later life has led Dr Adolf Meyer of New York, director of the State Pathological Institute, to inquire into the connexion, if any, between arterio-sclerosis and mental disease and an account of his studi is university students are generally much younger than with us, as 16 is a common age for a lad who is entering a university. At the university they have to pass two examinations—the first for the title of "licentiate" and the second for that of "doctor"—and medical students are obliged to go through both courses. They stay at the university about four years.

The medical school at Madrid is in a building distinct from the university and contains dissecting- and lecture-rooms and laboratories which were unfortunately closed for the vacation when I wished to see them.

Besides the ten universities enumerated above there have been others in Spain which are now closed—e g, that at Toledo, which was founded in 1438 and suppressed in 1807. The most typical and interesting, as well as the oldest, of the Spanish universities is that of Salamanca which was founded in Valencia in 1209 and transferred to Salamanca in 1240. The university of Salamanca played quite an important part in the history of Spain, for from it came almost all the distinguished Spaniards of the sixteenth and seventeenth centuries, though probably Don Quixote's "Bachelor of Salamanca" is the member of this university best known in England. It was to Salamanca that Gil Blas was going when he began his travels. The university was a most distinguished corporation and its representatives with the other grandees swore fealty to the kings of Spain at their accession, it received solemn visits from royal personages, as did our English universities under the Tudors and Stuarts, and, like Oxford and Cambridge also, it advanced money to the kings which was not always repaid. In 1710 the university of Salamanca gave to King Philip V 330 000 reals and 100 men whom they equipped for war and maintained as English nobles did in feudal times. The Popes on their election informed this university by special letters of their elevation to the Pontifical chair and sent cardinals as legates to visit it and to reform the abuses that crept into its administration, though the Spanish kings were jealous of their interference. Katharine, the daughter of John of Gaunt, presented 2000 florins of gold to the university and her son, King John II., gave to it a palace near to the university buildings for a hospital. John I had bestowed more than £7 annual income on Salamanca, which Henry III commuted for the third of the revenues from three townships, and the university maintained 70 professors and raised its magnificent buildings on this income, with the addition of one-ninth of the tithes of the bishopric of Santiago given by Pope Clement V. The university was governed by a rector and he and the professors were chosen annually by the scholars and Masters of Arts until the end of the sixteenth century. The meetings of the governing body were often boisterous and violent, at times the dignitaries even came to blows. When two professors lectured at the same hour they would often quarrel about their auditors and fees. Cervantes in one of his novels says that "students did not come to Salamanca to learn laws but to break them," and this was likely enough after the Reformation, for great numbers of Roman Catholics from Ireland, England, France, Germany, Flanders and Italy went there to be taught and no doubt quarrels were of frequent occurrence among young men of so many different nationalities. "The College of the Noble Irish" still exists and is a very handsome building, with spacious and stately rooms and a large library of old works on divinity and a score or two of modern books and even a very few novels among them. The college is somewhat out of repair and the wall paintings and furniture might be renewed with advantage. In its most flourishing time Salamanca numbered 10 000 students but now there are not 500. Salamanca itself is quaint and interesting—a typical old world Spanish city with a large square containing shops under a colonnade decorated with plaques of the heads of the kings of Spain and other distinguished persons, the latest of whom has been dead 200 years. The streets are narrow, the houses are tall with curiously wrought iron gratings to the windows which are far above the heads of the foot-passengers and there are many convents and churches and very beautiful pavements. In the main square where is now a garden there used to be bull fights formerly. The houses are mouldering away and the servants at the chief hotel are as ignorant of any tongue but their own as those at an inn in York or Exeter. In such a place it is easy to picture the old university life of which records have come down to us—the college inns, which were perilous to life and property even though they were licensed by the senate, the mess tables for the students, who were of all ages from mere boys to middle aged men, and the lads thrusting their left hands into the dish and hacking off with the knives which they carried in their boots or at their girdles their portions of meat and occasionally of other students' fingers, the brokers' shops for the sale of all sorts of clothes, both new and second hand, the 52 printing houses and 84 bookshops, employing 3600 persons, the broken meats given at the monastery gates to poor students and other beggars, the wine parties given by those who were canvassing for votes from the students in the professorial elections, the nocturnal adventures and serenades beneath those quaintly barred windows, the fights with the city watch and the other disputes and scandals which were always alarming the town and requiring the intervention of the rector—and small wonder, seeing how many young men from different proud and hot blooded nations were here assembled. The university was founded literally under the shadow of the Church and was never free from ecclesiastical influence and such influence is evident in all the educational institutions of Spain to this day. Students were not liable to any civil authority but were tried by the vice-chancellor—a practice which led to so many scandals that eventually the king appointed three conservators on behalf of the city to be assessors with the vice-chancellor when he tried the students for serious offences against the citizens.

An interesting feature of university life at Salamanca was the existence of a number of colleges in that city known as the "Greater Colleges" independent of, and even rivalling, the university itself. There were originally four Greater Colleges at Salamanca which were intended for students of theology and canon law and produced so many distinguished students that they eventually destroyed the prestige of the university. At first the competition between these Greater Colleges and the university was healthy for both, but the colleges became too great and wealthy and by the middle of the eighteenth century they had degenerated into hot-beds of vice and were so powerful as to be able to defy the reforms which were attempted. Before the French invasion there were six of these Greater Colleges in Spain, but the French suppressed all but two in Salamanca and one in Valladolid. Besides these so-called Greater Colleges there were four other colleges of the great military orders. These were established in spite of the opposition of the theological colleges and contested their supremacy, one of them—viz., that of the order of Calatrava—still survives. In addition to these there were several other smaller colleges also independent of the university, which are now represented by only one—that of St. Patrick, otherwise "The College of the Noble Irish," mentioned above. Each of these various colleges had its own rector and its own laws, and the result must have been a bewildering chaos. The architecture of those of the university buildings which remain is generally of the Renaissance style modified by Mauresque details, but some parts are Gothic, and so is the heating of the fine library by stoves with flues passing out through the ceiling. There is a very handsome door of hammered iron to the library. The collection of Greek and Latin codices is a very valuable one and has been augmented by those removed from the libraries of the Greater Colleges and from those of the Jesuits and of other convents which have been suppressed.

The university of Granada has now but 500 or 600 students. The university buildings were erected by the Jesuits and are very large and well adapted for their purpose.

Valladolid university (founded in 1346) has about 1000 students, about one-fourth of whom take up medicine, in which faculty there are 16 lectureships with a clinical professor, two assistants, and "a corresponding number of resident pupils." The hospital was built in 1857.

The university of Valencia was founded in 1441 and has now about 2000 students. In this town there is also an independent college (del Patriarca) like the College of St. Patrick at Salamanca.

Barcelona has a university which was founded in 1450. The present buildings are modern dating from 1873. The library contains 160 000 volumes and has a reading room for 120 students. There are about 2500 students here.

The rector of a Spanish university can have but little time to devote to his university, for he has to supervise the schools of all classes in his district, which may include several provinces, he is also president of the "consultative university council" of the district which council is composed of the deans of the faculties, of the directors of the superior schools, and of other persons nominated by the Government, 6600 observations have been kept by its inspectors, 4623 nuisances have been reported, 4423 reports have been notified to local authorities, and 330 summonses have been issued, the total fines amounting to £1287 There can be no doubt that considerable practical good has been effected, and if we do not entirely owe the presence of spring during the winter months of January and February to the Coal Smoke Abatement Society we see no reason why the society should not claim credit for a proportion of our unwonted sunshine Among the speakers at the meeting at Grosvenor House, in addition to the President, were Dr H. A. Des Vœux (the treasurer of the society), Lord Robert Cecil, K.C , Sir James Crichton Browne, F R.S , and Mr W D Caröe, and full testimony was borne by all of them to the injury which coal smoke does to the public health and to its demoralising effect upon the people The report of the society, which contains some very instructive illustrations, can be obtained at 25, Victoria street, Westminster, S W

THE LATE MR W J C MILLER

In our issue of Feb 21st, p 541, we announced the death of Mr W J C Miller who will be known to most of our readers, if not to all, as the late registrar of the General Medical Council. His death occurred on Feb 11th from bronchitis following influenza, but for some years past he had been suffering from hemiplegia William Miller was born in 1832 and was educated at the West of England Dissenters' Proprietary College, Taunton. One of his fellow scholars there was the late John Wale Hicks who entered the medical profession and who, afterwards taking holy orders, became Bishop of Bloemfontein Mr Miller on leaving Taunton became a teacher at Huddersfield and here began his connexion with the *Educational Times* of which journal he was mathematical editor for nearly 40 years In 1876 he was appointed registrar to the General Medical Council and took up his abode at Richmond, where he wrote those charming essays about bird life upon many of which we have commented in our pages. In November, 1896, during the session of the General Medical Council, he suffered from aphasia and finally sent in his resignation on May 21st, 1897 The Council had no power to grant a pension, but Mr Miller was presented with £1000 as a gratuity A faithful servant of the medical profession he practically finished his life's work in harness His last days were passed at Bournemouth.

THE PREVALENCE OF SMALL-POX

The Local Government Board for Scotland intimates that during the period from Feb 1st to 15th inclusive 2 cases only of small-pox have been notified to it—viz , another case in Leith Burgh and 1 intimated from Grangemouth Burgh, the case of a seaman on board a ship which arrived at the latter port on Feb 12th

The 130th anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms, Hôtel Métropole, on Saturday, March 7th, at 7 30 p m Mr A. Pearce Gould, the President, will take the chair In addition to the Presidents of the Royal College of Physicians of London, of the Royal College of Surgeons of England, and of the "Sister Societies," the President and Council will have the honour of including among their guests the Lord High Chancellor, Lord Sandhurst, the Hon. Robert P Porter, late U S A. Commissioner in Cuba, Mr Balfour Browne, K C , Mr Montague Lush, K.C , Sir Thomas Smith, Bart., K.C V O , and Sir Thomas Barlow, Bart., K.C V O

Sir Henry Burdett, K.C B., will open a discussion at the Caxton Hall, Westminster, on March 3rd, before a meeting of the Hospitals Association, on Hospital Sites and Population in London Ought any, and if so which, of the large hospitals to be moved from their present sites to new ones situated (*a*) in more congested districts or (*b*) in the country? Sir Trevor Lawrence, Bart , treasurer of St. Bartholomew's Hospital, will take the chair at 5 p m. and tickets can be obtained on application to Mr Sydney Phillips at St. Thomas's Hospital.

The death is announced on Feb 18th of Dr Thomas Peregrine, formerly of Half Moon street Dr Peregrine was in his ninety third year He was educated at St George's Hospital and at Edinburgh University where he took the degree of M D in 1833. He became a Member of the Royal College of Surgeons of England in 1837 and a Member of the Royal College of Physicians of London in 1859 He was also at one time Senior Warden and a member of the Court of Examiners of the Society of Apothecaries of London.

A sessional meeting of the Sanitary Institute will be held at the Parkes Museum on Wednesday, March 11th, at 8 p m., when a discussion will take place on Sewage Disposal and the Qualities essential in a Sewage Effluent. The discussion will be opened by Dr George Reid, medical officer of health to the Staffordshire county council, and a general discussion will follow

At the next meeting of the Society of Anæsthetists on March 6th, at 8 30 p m , Mr A. Vernon Harcourt, F R.S , will read a paper on, and will show, his new chloroform regulating inhaler by which the percentage of chloroform in the vapour inhaled can be, it is claimed, positively controlled. All members of the medical profession are invited to be present.

The report of the Departmental Committee appointed by the Home Secretary four months ago to draft a scheme for the regulation of cremation proceedings has been issued The suggestions of the committee are clear and careful and have important medical bearings to which we shall shortly have occasion to direct attention.

THE UNIVERSITIES OF SPAIN

(From a Special Correspondent)

Spain is divided for educational purposes into ten districts, each with a university—viz., Madrid, Barcelona, Valencia, Seville, Granada, Valladolid, Santiago, Saragossa, Salamanca, and Oviedo There is a faculty of medicine at each of these universities except at Salamanca and Oviedo Each faculty is ruled by a dean (who receives from £190 to £220 per annum) and there are from 16 to 19 professors who are paid from £102 to £175 yearly according to seniority , one professor at Barcelona has an income of £245. At Madrid there are five extraordinary professors for the M.D degree, as it is almost exclusively in this university that this degree is obtained, but these professors are not more highly paid than are the rest. There are in all about 16 000 students at these ten universities and of these about 7000 are studying medicine, for in Spain every medical man must have a university degree to qualify him for practice. This rule is not an absolute guarantee of the efficiency of the practitioner, for a boy may enter the university at 12 years of age and be a fully qualified doctor at 16 and may then practise if he can find patients to trust him or a newspaper to advertise his precocity, as sometimes happens.

University students must first go through the curriculum at one of the *institutos* or schools for middle class boys who receive a higher education than do the pupils in the State schools which latter are equivalent to our board schools Boys who have finished their school training pass an examination and receive the degree of Bachelor (B A), which is a necessary step before they can be admitted to a university, so that this examination is equivalent to matriculation in an English university Spanish they would whirl round the angles so dexterously, and skip up two or three stairs at a step, that before all the young vultures after knowledge were fairly into a ward, the surgeon general for the week would be deliberately pacing the next, and this used to be called 'Hospital Practice.'" "True, said I, but how is it now?" "Now! why it is altogether different, as you will soon have an opportunity of observing and here is the instrument that has effected the change (pulling from his pocket one of your Lancets, Mr. Editor,) you see what is said here of 'Hole and Corner Surgery,' well, they were so phlebotomised with this Lancet, that they have been completely cured of their *cynanche* and sullenness, and the point of consistency is now exceeded as much as their exertions before fell short of their duties. We have quite an overflow of instruction, quite a gratuity of prelections, we have clinicals upon clinicals, demonstrations, observations and examinations following so closely the heels of each other, that we have scarcely time to digest our dinners, much less the discourses."

I felt highly gratified at the explanation my old acquaintance had given, and could not resist the strong inclination I felt of thanking you, Sir, for the beneficial change which has been effected in the Borough, and have to request, for the benefit of the younger members of the profession that you will shortly explore other *dark places of the earth*, and rid them of their malpractices as effectually as you have done the "holes and corners of St Thomas's Hospital.

Yours truly,
A TOURIST.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8433 births and 4841 deaths were registered during the week ending Feb. 21st. The annual rate of mortality in these towns, which had been 18 1, 17 9 and 17 1 per 1000 in the three preceding weeks, further declined last week to 16 7 per 1000 In London the death rate was 17 6 per 1000, while it averaged 16 4 per 1000 in the 75 other large towns. The lowest death rates in these towns were 4 1 in Burton-on-Trent and in King's Norton, 7 4 in Willesden, 7 9 in Aston Manor 8 0 in East Ham, 8 7 in Birkenhead, 8 9 in Smethwick and in Tynemouth, and 9 1 in Handsworth, the highest rates were 20 4 in Burnley 21 0 in Wigan, in Salford, and in Oldham, 21 2 in Liverpool, 21 4 in Hanley and in Rhondda, 23 3 in South Shields and 24 1 in Great Yarmouth. The 4841 deaths in these towns last week included 452 which were referred to the principal infectious diseases, against 493 512, and 457 in the three preceding weeks, of these 452 deaths 120 resulted from whooping-cough, 94 from measles, 78 from diphtheria, 70 from diarrhœa, 49 from scarlet fever, 28 from 'fever' (principally enteric) and 13 from small pox. No death from any of these diseases was registered in Hastings Plymouth, Burton-on Trent, Handsworth, King's Norton, Aston Manor Grimsby Wallasey, St Helens Warrington, Gateshead, or Newport (Mon.), while the highest death rates from the principal infectious diseases were recorded in Devonport, Stockport Wigan, Manchester, Oldham, Preston, Rotherham, and Middlesbrough. The greatest proportional mortality from measles occurred in Devonport, Wigan, Salford, and Middlesbrough, from scarlet fever in Stockport and Oldham, from diphtheria in Hanley and Bury, from whooping-cough in Hornsey Southampton Great Yarmouth, Stockport, Oldham Preston, Rotherham, and Rhondda, and from "fever in Middlesbrough Six fatal cases of small pox were registered in Liverpool two in Manchester, two in Leeds, and one each in Birmingham, Oldham, and Rotherham. The number of small pox patients under treatment in the Metropolitan Asylums hospitals which had been seven, six, and six at the end of the three preceding weeks, had increased to eight at the end of last week seven new cases were admitted during the week, against six four and one in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday Feb. 21st, was 1893, against numbers declining from 2528 to 1919 on the eight preceding Saturdays, 206 new cases were admitted during last week, against 228, 189 and 246 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 355, 315, and 257 in the three preceding weeks, rose again last week to 274 but were 218 below the corrected average number. The deaths in London directly attributed to influenza numbered 25 last week, having been 25, 39, and 24 in the three preceding weeks The causes of 62, or 1 3 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Manchester, Salford, Leeds, Newcastle-on-Tyne, and in 44 other smaller towns, the largest proportions of uncertified deaths were registered in Leyton, Hanley, Liverpool, St. Helens, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21 3, 21 7 and 18 1 per 1000 in the three preceding weeks was again 18 1 per 1000 during the week ending Feb. 21st, and was 1 4 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11 3 in Greenock and 12 4 in Leith to 22 6 in Aberdeen and 24 8 in Perth. The 592 deaths in these towns included 26 which were referred to whooping-cough, 18 to diarrhœa, 12 to measles, eight to "fever," seven to scarlet fever, and five to whooping cough, but not one to small pox. In all, 76 deaths resulted from these principal infectious diseases last week, against 81, 80, and 85 in the three preceding weeks. These 76 deaths were equal to an annual rate of 2 3 per 1000 which was 0 7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 28 and 32 in the two preceding weeks, declined again last week to 26, of which 20 were registered in Glasgow, two in Dundee, and two in Paisley The deaths from diarrhœa, which had been 19 and 16 in the two preceding weeks, rose again last week to 18, and included eight in Glasgow, five in Dundee, and three in Edinburgh. The fatal cases of measles, which had been 20, 16, and 15 in the three preceding weeks, further declined last week to 12, of which 10 occurred in Aberdeen and two in Edinburgh. The deaths referred to different forms of "fever,' which had been five, six, and 11 in the three preceding weeks, declined again to eight last week, and included seven in Glasgow The fatal cases of scarlet fever, which had been four four, and eight in the three preceding weeks declined again last week to seven, of which three occurred in Glasgow and two in Paisley The deaths from diphtheria, which had been seven and three in the two preceding weeks rose again to five last week, and included two in Edinburgh and two in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 173, 134 and 112 in the three preceding weeks, further decreased last week to 109, showing a decline of 115 from the number in the corresponding period of last year The causes of 23, or nearly 4 per cent. of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 24 8, 26 4, and 25 0 per 1000 in the three preceding weeks, further declined to 20 6 per 1000 during the week ending Feb. 21st During the past four weeks the death rate has averaged 24 2 per 1000 the rates during the same period being 17 5 in London and 16 1 in Edinburgh. The 150 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 32 from the number in the preceding week, and included 18 which were referred to the principal infectious diseases, against 10 nine, and four in the three preceding weeks, of these, six resulted from measles, four from scarlet fever, three from diphtheria, three from whooping-cough, one from fever, and one from diarrhœa. These 18 deaths were equal to an annual rate of 2 5 per 1000 the death rates last week from the same diseases being 1 9 in London and 1 3 in Edinburgh. The six fatal cases of measles showed an excess of four over the number in the preceding week The deaths from scarlet fever which had been three, two, and three in the three preceding weeks further rose last week to four The fatal cases of diphtheria, which had been three and one in the two preceding weeks, rose again to three last week. The three deaths from whooping-cough corresponded with the number in each of the two preceding weeks. The 150 deaths in Dublin last week included 21 of children under one year of age and 37 of persons aged 60 years and upwards, the deaths both of infants and of elderly persons showed a considerable decline from the numbers recorded in and he has also to keep in good humour the various civil governors of the provinces in his district who are appointed by the Government and are *ex officio* chairmen of what may be considered as the school board of the province. Probably the universities suffer from the multifarious character of the rectorial duties, though the general education of each district may be benefited by this superintendence The State appoints, or approves of the appointment of, all the heads of the educational department in each province, but education in Spain is still cramped and limited by ecclesiastical interference, as it was in the time when the university of Salamanca was in its most flourishing state. The annual cost of the Spanish universities is borne by the State and is nominally about £130,000, but against this must be set the large sum which is paid by the students for university fees, so that the universities are no great burden on the Spanish exchequer

MEDICINE AND THE LAW

Frauds by a Pretended Medical Man.

AN impostor named Bruno Kohnfeldt was sentenced on Feb 18th at Clerkenwell sessions to four years' penal servitude for a series of frauds after previous convictions and his female accomplice to a shorter term of imprisonment The case is worthy of the attention of medical men and of members of other learned professions, because it shows how easily they may become the victims of begging letter writers owing to their names appearing with their addresses in official directories and also how a little care and trouble may sometimes expose fraud of this kind. Kohnfeldt's plan was to represent himself as a medical man benevolently interested in a patient in reduced circumstances. The person on whose behalf he solicited assistance was stated to have been at college with the person addressed and a university calendar supplied a suitable name. He presumably took his chance as to the person addressed having more or less lost sight of the person written about, as he also accepted the risk of what might occur if inquiry was made. To take an example from the evidence of a particular case given at the police-court, Kohnfeldt wrote to the Bishop of London saying that he had attended in illness a gentleman named who had in fact been a fellow undergraduate of his lordship at Keble College and who, he alleged, was now in poverty and bad health, so that a contribution towards buying him a small business would be of assistance The bishop accordingly directed his private secretary to send £5 The story was a plausible one, but at the same time it was one not difficult to sift. The impostor described himself as "Dr Charles McCann" and wrote from an address in Bloomsbury Inspection of the Medical Directory would have shown that Mr Charles McCann, therein described with his qualifications, had retired from practice and neither the Medical Directory nor the Medical Register would have lent any colour to the suggestion that he was practising in Bloomsbury If, however, no such work of reference was at hand the ordinary Post-office Directory would have afforded presumptive evidence that Dr McCann did *not* live at the address given, which was that of a hairdresser who took in Kohnfeldt's letters. The name of the person for whom assistance was asked is to be found in the Oxford University Calendar as a contemporary of Bishop Ingram, and that is presumably where Kohnfeldt obtained it, having access to one of the free libraries that are now common in the metropolis. The latest edition of the calendar however, shows that the name of the gentleman in question is still borne on the books of his college and that he is a doctor of medicine. Again the Medical Directory or Medical Register might have been referred to, and would have shown him apparently carrying on a practice not far from London, where direct communication might have been opened with him. As an alternative a letter to Keble College would have presumably elicited information, as members of a college who have taken doctors' degrees are not usually altogether lost sight of by their *alma mater* In another case upon which Kohnfeldt was convicted the person duped was a clergyman and so was he on whose behalf aid was solicited, his name appearing as such in the Oxford Calendar, while his address is given in the Clergy List. Books of reference of this kind may not be in every house, but they are usually to be found in club libraries and other places accessible to those whose pecuniary position enables them to be liberal as well as kind hearted, as well as in the free libraries, where they are at the service of any knave who chooses to make use of them. Indiscriminate charity does more harm than good even where no direct fraud, such as that described, is attempted, while inquiry may enable the generous to give substantial assistance in cases where help is needed and likely to be effective

Looking Back.

FROM

THE LANCET, *SATURDAY*, FEB 26, 1825.

ST THOMAS'S HOSPITAL.

To the Editor of THE LANCET

SIR,—If I should begin my letter as most persons do, who wish to procure an early insertion, I should say that I have derived much pleasure from the perusal of your *extensively circulated* Journal, but this would be telling you a sort of truism, for although some of your remarks are severe and searching and some prudishly hint that *The Lancet* is a little too sharp, yet all the physicians, surgeons, midwifers, and apothecaries, within the scope of my acquaintance, read it with avidity, and, I suppose, do so for the same reason that I have lately done, because they reap from it information and amusement. Now I have always heard you described as a *hic et ubique*—a here, there, and everywhere sort of gentleman,—assuming such a questionable shape, that I have seen four individuals, unless "mine eyes are made the fools o' the other senses," as different in their figures and physiognomies as the four *Prices* of city notoriety, represented each as the Editor of the Lancet. Pray be good enough to inform me, Sir, if you have the wonderful faculty of splitting yourself into quarters, and sprouting up entire "*Dramatis Personæ*," in as many distant places at the same time? Or is your presence, "the terror of evil doers," imaginary only, the mere false creation of perturbed minds and misgiving consciences? Indeed I am inclined to think that the latter conjecture is correct, for, as M Ragniot and I were walking quietly through the wards of St. Thomas's Hospital one afternoon, we came unnoticed behind a gentleman who was soliloquizing by a window, his mood was pensive, and his eyes directed to the floor, as we came nearer, we heard him repeating what we deemed a parody on the words of Macbeth He proceeded thus—

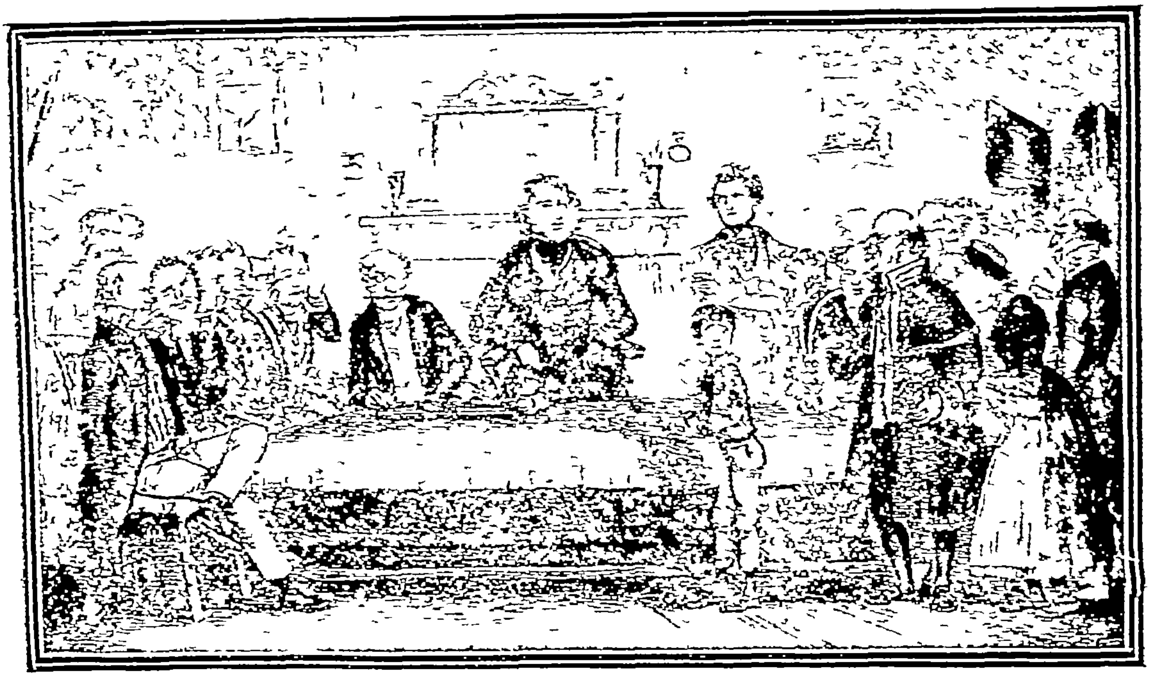
> "Is this a *Lancet* which I see before me ,—
> Or art thou but a dagger of the mind,—a—?
> I have thee not, but—let me clutch thee once—and—"

then he stamped on the floor, which roused him from his reverie, and observed us, and made a sudden retreat, looking very dejected. Our appearance unfortunately interrupted him, or we should certainly have been favoured with some further disclosure of this "mind diseased." Had we heard a man muttering thus in another part of the building, we should have set him down a "*Hospital idiot*," but how were we surprised to find from the nurse that the unfortunate gentleman, who had just left the ward, belonged to a society of men called in this country "*pure* surgeons" This was a strange sort of adventure, and neither M R nor myself could make it out for some time, but my companion at last suggested that he had either bled some poor mortal to death, or that he intended to commit an act of *felo de se* with the same little instrument.

I was not satisfied however, with this, and determined to extend my ramble in hope of gaining further information, and fortunately met with an old pupil, to whom I communicated what I had seen. He laughed heartily, and then began to unravel the mystery "Oh! said he, since you have been on the Continent, there has been quite a revolution in the professional discipline of the hospitals, you know what used to be called going round the wards with the surgeons, the most you could ever extract from them were monosyllabic answers to questions, however interesting or important. Mum was the order of the day, as if their air passages were hermetically sealed, or as if they laboured under *cynanche laryngitis*, so that every attempt at articulation produced pain. As to anything in the shape of a 'practical observation,' that was quite out of the question,

THE FOUNDER OF THE LANCET

THE picture below is an excellent reproduction of an old print illustrating a parish inquest being conducted by the late Thomas Wakley The original sketch was obviously made from life, as Mr. Wakley's features are faithfully reproduced. The figure with folded arms standing at the coroner's left hand probably represents Charles Dickens who attended many of Wakley's parish inquests and obtained in this way some of his lurid information upon the working of the Poor law between 1835 and 1860. The picture occurs in a little book entitled "Scenes in London" in the possession of Mr O van Noorden. Our illustration is from a block very courteously and kindly placed at our disposal by the proprietors and the editor of the *Sphere*, in which paper the illustration recently appeared.



A Parish Inquest before Thomas Wakley M.P., Coroner for West Middlesex.

"Audi alteram partem."

ASEPTIC AND ANTISEPTIC SURGERY

To the Editors of THE LANCET.

SIRS,—Mr. Cuthbert S Wallace's letter in THE LANCET of Feb 14th, p. 475, shows that the views put forward by Mr Watson Cheyne in your issue of Feb. 7th may give rise to differences of opinion. I should therefore like to express my firm belief in Mr Cheyne's statement that "aseptic surgery as at present defined—that is to say, surgery without the use of antiseptics—is impossible." I have not attempted to work by the aseptic method but I have had the opportunity of watching others doing so The results are uncertain and failure to avoid septic infection by this method does not depend on the magnitude of the operation or on the gravity of the complications to be dealt with. Failure is as likely to occur in a simple as in a difficult case.

Aseptic surgery may be described as theoretically perfect surgery But thorough disinfection of the skin without antiseptics is not possible and if the aseptic system teaches, as Mr. Wallace states, that "hands should be kept out of wounds or covered with boiled rubber gloves," the conditions must hamper the operator in abdominal surgery to a degree which, from this one stipulation alone, renders the system impossible. Aseptic surgery requires more care and more skilled assistance than antiseptic surgery does and it is difficult enough to get antiseptic precautions carried out, especially in private houses. Recently I had my attention directed to an error which Mr Cheyne has also noted. A patient pointed out that her nurse applied a compress so dry that it must have been useless This was a fault of teaching or of comprehension. I have more than once found on going to operate in a private house that although the nurse had done her best she had quite failed to obtain any water which had not an obvious sediment. Antiseptic surgery is difficult and dangerous in such circumstances and it is quite impossible to give effect to the more minute precautions necessary for aseptic surgery

I am convinced that Mr. Cheyne is right when he states that the elaborate arrangements with which the aseptic surgeon surrounds himself in his hospital practice in order to prevent all contamination of his wounds are apt to take away the attention of nurses from essential details, and it is certain, as Mr Wallace points out, that this should not be attributed to the system, but when Mr. Wallace declares that 'a student or nurse trained in the antiseptic school is prone to place too much reliance on a wash in chemicals and too little in hot water and soap" the same objection holds good that this is not attributable to the system. The antiseptic system teaches that everything connected with a wound—hands, instruments patient's skin, &c —should be made as clean as possible by all ordinary methods and by the use of antiseptics. In recent years after everything has been made thoroughly clean, I have had all instruments boiled that do not spoil by boiling and I use antiseptic solutions as I did before I resorted to the practice of boiling for disinfecting purposes. I have formed a very firm opinion that many nurses who ought to know better have a tendency to consider the cleaning of instruments less important when they are to be boiled and, I think some surgeons act on this principle also. I do not suppose this is the result of any teaching but in my opinion the idea that the most careful cleansing of instruments is not essential to the best results is very strongly to be deprecated. Perfect cleansing is not essential to an individual success or even to a series of successes, but it is essential to the attainment of the best and most constantly successful results.

the preceding week. Four inquest cases and three deaths from violence were registered, and 54, or more than a third, of the deaths occurred in public institutions. The causes of six, or 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES

Royal Navy Medical Service.

THE following appointments are notified:—Staff Surgeon J. H. Stenhouse to the *Boscawen*. Surgeons R. R. Fasson to the *Vivid*, for Keyham Yard; P. K. Nix to Plymouth Hospital; G. Gibson to R.M. Depôt, Deal; E. S. Reid to R.M. Artillery; and H. Spicer to the *Royal Oak*.

The undermentioned Surgeons have been advanced to the rank of Staff Surgeon in His Majesty's Fleet:—Thomas Christopher Meikle, Joseph Cudlip Wood, Horace Bruce Marriott, Norman Lloyd Richards, Ernest Alfred Penfold, Ernest James Finch, John Kirkup Robinson, and Hugh Clift.

Royal Army Medical Corps.

The date of retirement of Lieutenant-Colonel T. B. A. Tuckey is Jan. 6th, 1903.

Lieutenant-Colonel F. W. Trevor to be Colonel, vice J. L. Notter, retired. Dated Jan. 14th, 1903.

The undermentioned Majors to be Lieutenant-Colonels (dated Feb. 3rd, 1903):—W. G. Macpherson, C.M.G., R. J. S. Simpson, C.M.G., E. V. A. Phipps, A. Baird, T. W. O'H. Hamilton, C.M.G., D. Semple, J. R. Stuart, and R. P. Bond.

Army Medical Reserve of Officers.

Surgeon Major G. F. England to be Surgeon Lieutenant-Colonel (dated Feb. 1st, 1903); Surgeon Lieutenant W. O. Evans to be Surgeon Captain (dated Feb. 21st, 1903).

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 1st Lanarkshire: Surgeon Lieutenant-Colonel J. S. Cumming resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement. Dated Feb. 21st, 1903.

Rifle: 3rd Volunteer Battalion the Lincolnshire Regiment: Surgeon-Major F. J. Walker to be Surgeon Lieutenant-Colonel. Dated Feb. 21st, 1903. 4th (Cambridge University) Volunteer Battalion the Suffolk Regiment: Supernumerary Surgeon Lieutenant R. W. Mitchell to be Surgeon Captain. Dated Feb. 21st, 1903. 1st Lanarkshire: Surgeon Captain R. C. Lees to be Surgeon Major. Dated Feb. 21st, 1903. 1st Cadet Battalion the King's Royal Rifle Corps: St. John Frank Blake Campbell to be Surgeon Lieutenant. Dated Feb. 10th, 1903.

Volunteer Infantry Brigade Bearer Company.

2nd London: The transfer of the undermentioned officers from the 5th Middlesex (West) Volunteer Rifle Corps bears date April 16th, 1902, viz.:—Captain J. N. Brown and Lieutenant E. C. Montgomery Smith.

Royal Army Medical Corps.

The following is a list of appointments as Lieutenants in the Royal Army Medical Corps:—

*A. R. Smallman
†W. F. Tyndale, C.M.G.
P. Davidson, D.S.O.
‡J. McKenzie.
§W. B. Taylor.
N. D. Walker.
A. H. Hayes.
H. J. Crossley.
R. B. Ainsworth.
C. A. J. A. Balck.
R. Storrs.
R. L. V. Foster.
F. A. H. Clarke.
G. A. K. H. Reed.
G. W. Smith.
J. W. S. Sucombe.
J. M. H. Conway.
S. M. W. Meadows.
H. V. Bagshawe.
D. S. Skelton.
C. V. B. Stanley.
H. G. S. Webb.
W. W. Browne.
R. Rutherford.
W. D. C. Kelly.
N. E. J. Harding.
W. C. Rivers.
R. J. Franklin.

* Gained the Herbert Prize and the Parkes Memorial Bronze Medal.
† Gained the prize in Pathology.
‡ Gained the Marshall Webb Prize.
§ Gained the De Chaumont Prize and the prize given for Aldershot [illegible]

Tuberculosis in the French Army.

In the exordium of his new work "La Tuberculose dans l'Armée"[1] Inspector General A. Kelsch makes the discouraging avowal that in spite of all the prophylactic measures which have been enforced for upwards of ten years tuberculosis is still progressing in the French army. The percentage of cases is greater than it used to be but the cause of the increase is solely due to the prevalence of the disease amongst young soldiers. The veterans suffer to a much less extent than they did formerly—a reassuring fact which is taken as proof of the practical efficacy of preventive medicine. Recruits on joining are either already contaminated with the germs of the complaint or else, owing to their imperfect constitutional defences, they are unable to resist the infection to which in their new mode of life they necessarily become exposed. Inspector General Kelsch lays stress upon the extreme importance of the secondary causes in the genesis of tuberculosis. Doubtless the bacillus is the immediate agent in the production of the disease, but not even the most virulent of microbes can prevail where the fortifications are effective. The most solid foundation upon which to erect the rampart of prophylaxis is the development of physical vigour, together with the amelioration of hygienic and social conditions.

New Regulations for Probationers of the Indian Medical Service.

The Secretary of State has sanctioned the following changes in conditions in order to place probationers of the Indian Medical Service on the same footing as those of the Royal Army Medical Corps:—(1) Their title to be changed from surgeon on probation to lieutenant on probation; (2) their pay (exclusive of allowances) to be raised to 14s. a day; (3) their commissions as lieutenants to bear the date on which their course of instruction begins, their appointments not, however, being gazetted until they have passed the final examination; and (4) a lieutenant on probation who at the time of passing the examination for admission to the service may hold, or be about to hold, a resident appointment in a recognised civil hospital to be seconded, if fully approved, for one year; while seconded, such officer shall receive no pay from Indian funds, but his service in the civil capacity may be allowed to reckon towards promotion and increase of pay and pension.

The Alexander Memorial Prize.

The prize of £50 and the gold medal of the Alexander Memorial Fund for 1902 have been awarded to Major F. Smith, D.S.O., R.A.M.C. The subject for the next competition is "Syphilis in the Army and its Influence on Military Service, its Causes, Treatment, and the Means which it is Advisable to Adopt for its Prevention." Essays must reach the president of the committee on or before Dec. 31st, 1905, must bear a brief motto, and must be accompanied by a sealed envelope similarly superscribed, containing the name and address of the author. No essays should exceed about 20,000 words exclusive of tables which may be added in the form of appendices. The competition is limited to executive officers of the Army Medical Staff on full pay, and professors and assistant professors at Netley are not eligible while so employed.

Deaths in the Services.

Surgeon-Lieutenant Colonel Edward Eustace, A.M.D. (retired), at his residence, Underwood, Cheltenham, on Feb. 16th, in his sixty-second year. He entered the army as assistant surgeon in 1864, became surgeon in 1873, and surgeon major in 1876, retiring in 1885 with the rank of surgeon lieutenant-colonel.

Staff Surgeon Narcissus Collins Hatherly, R.N. (retired), at South Molton, Devon, on Feb. 10th, in his eightieth year. He entered the service in 1845 and became staff surgeon on his retirement in 1862. He was senior medical officer of the expedition in the boats of the *Alarm* and *Vixen* up the San Juan de Nicaragua and was present at the storming of Fort Serapique, 1848 (mentioned in despatches).

The Indian Medical Service Examination.

A competitive examination for appointments to His Majesty's Indian Medical Service will be held at the Examination Hall, Victoria Embankment, London, about Midsummer next. The number of vacancies for competition and the date of commencement of the examination will be notified hereafter. Application for the regulations for admission to the Indian Medical Service should be addressed to the Under Secretary of State for India, India Office, Whitehall, London, S.W.

The Commander in Chief has had conveyed to Lieutenant-Colonel B. M. Skinner, R.A.M.C., Secretary of the Army Medical Service Advisory Board and of Queen Alexandra's Imperial Military Nursing Service, his appreciation of that officer's good service in South Africa, where he was principal medical officer of a division.

ASEPTIC AND ANTISEPTIC SURGERY

To the Editors of THE LANCET.

SIRS,—Mr Cuthbert S Wallace's letter in THE LANCET of Feb 14th, p. 475, shows that the views put forward by Mr. Watson Cheyne in your issue of Feb. 7th may give rise to differences of opinion. I should therefore like to express my firm belief in Mr Cheyne's statement that "aseptic surgery as at present defined—that is to say, surgery without the use of antiseptics—is impossible.' I have not attempted to work by the aseptic method but I have had the opportunity of watching others doing so The results are uncertain and failure to avoid septic infection by this method does *not depend on the* magnitude of the operation or on the gravity of the complications to be dealt with. Failure is as likely to occur in a simple as in a difficult case.

Aseptic surgery may be described as theoretically perfect surgery But thorough disinfection of the skin without antiseptics is not possible and if the aseptic system teaches, as Mr. Wallace states, that "hands should be kept out of wounds or covered with boiled rubber gloves," the conditions must hamper the operator in abdominal surgery to a degree which, from this one stipulation alone, renders the system impossible. Aseptic surgery requires more care and more skilled assistance than antiseptic surgery does and it is difficult enough to get antiseptic precautions carried out, especially in private houses. Recently I had my attention directed to an error which Mr. Cheyne has also noted. A patient pointed out that her nurse applied a compress so dry that it must have been useless This was a fault of teaching or of comprehension. I have more than once found on going to operate in a private house that although the nurse had done her best she had quite failed to obtain any water which had not an obvious sediment. Antiseptic surgery is difficult and dangerous in such circumstances and it is quite impossible to give effect to the more minute precautions necessary for aseptic surgery

I am convinced that Mr Cheyne is right when he states that the elaborate arrangements with which the aseptic surgeon surrounds himself in his hospital practice in order to prevent all contamination of his wounds are apt to take away the attention of nurses from essential details, and it is certain, as Mr Wallace points out, that this should not be attributed to the system, but when Mr Wallace declares that "a student or nurse trained in the antiseptic school is prone to place too much reliance on a wash in chemicals and too little in hot water and soap" the same objection holds good that this is not attributable to the system. The antiseptic system teaches that everything connected with a *wound—hands, instruments, patient's skin, &c —should* be made as clean as possible by all ordinary methods and by the use of antiseptics. In recent years, after everything has been made thoroughly clean, I have had all instruments boiled that do not spoil by boiling and I use antiseptic solutions as I did before I resorted to the practice of boiling for disinfecting purposes. I have formed a very firm opinion that many nurses who ought to know better have a tendency to consider the cleaning of instruments less important when they are to be boiled and, I think some surgeons act on this principle also. I do not suppose this is the result of any teaching but in my opinion the idea that the most careful cleansing of instruments is not essential to the best results is very strongly to be deprecated. Perfect cleansing is not essential to an individual success or even to a series of successes, but it is essential to the attainment of the best and most constantly successful results.

Another question raised by Mr Cheyne and Mr Wallace is the burying of sutures and I am surprised to find that both consider the burying of silkworm gut permissible. Of course it is possible to bury silkworm gut without inducing sepsis, but I have seen an abdominal scar with the ends of buried silkworm gut sutures like so many pinpoints easily felt under the skin. There could be no peace for the patient until they were removed and it seems to me obvious that a material so stiff should not be used in this way The question of suturing abdominal wounds in layers is too large to enter upon here but I am well content with the results, so far as I know them in my own practice, in which I very seldom sew up a wound in layers I have an objection to buried sutures which is not connected with sepsis. In several cases I have found silk sutures within the abdominal cavity which were apparently in process of absorption but which gave rise to tenderness , on removing them there was no evidence of any septic irritation and certainly no abscess had formed. I therefore always use the silk as thin as possible, often risking a break in tying rather than use a coarser thread. By gradual pressure a very fine ligature may be made to serve where a stronger one is necessary if extreme rapidity in tying it is desired For this reason, which is not connected with septic mischief, I am induced to use silk more sparingly than I have done in the past, although I do not care to risk the tying of an ovarian pedicle or uterine tissues for the arrest of hæmorrhage with catgut I am Sirs, yours faithfully,

Portman street, W Feb 23rd 1903 JOHN D MALCOLM.

To the Editors of THE LANCET

SIRS,—I have read with interest and not without astonishment Mr W Watson Cheyne's criticism of aseptic surgery at the annual meeting of the Harveian Society of London and published in THE LANCET of Feb 7th, p 347 It is perfectly evident that Mr Watson Cheyne is no friend of aseptic methods but is so wedded to the use of antiseptics that he will not take the trouble (that is the word) to give the newer method a fair trial. If he would only do so I am quite sure he would be struck by the improvement in the treatment and condition of the wounds under his care. There seems to be some misconception, to use a mild phrase, as to what aseptic means Mr Watson Cheyne's description of aseptic methods is not very full nor is it very convincing There are far too many omissions in it. It is quite true that the term "aseptic" was defined by Mr Watson Cheyne in his work on antiseptics published in 1882 , but with advancing time and knowledge the same condition can be brought about more thoroughly by means of heat, as regards dressings and instruments, than it can by chemicals Aseptic surgery is described by Mr Watson Cheyne's colleagues, Mr W Rose and Mr A. Carless, as the attempt "to eliminate the irritating properties of chemical antiseptics."

To my mind the great principle which underlies the teaching of aseptic surgery is overlooked by those who largely employ antiseptics. In the latter the student has it thoroughly impressed upon him that he must use carbolic or perchloride lotion, iodoform and boric powder to cover the wound and over all medicated gauze. Having used all or any of the above he has discharged his whole duty to his patient. "He used antiseptics " What we want to get him to understand is that a condition of perfect cleanliness (bacteriological) should be arrived at of his hands and the parts to be operated upon and all materials used for the operation. He is not to trust altogether to his chemicals—something else is wanted and I think that *something* is more enforced under modern aseptic than antiseptic methods It is certainly true that more personal supervision of detail is required in aseptic than in antiseptic surgery, but it is in detail that it tells—in details it counts Both schools use antiseptics or chemicals for the production of asepsis of hands and parts to be operated upon, but in the antiseptic school the preparations are not so complete nor so thorough as in the aseptic.

It should be impressed on the student that the attention to minute details preceding an operation is of more importance than the use of preventives during an operation where the preliminary details have been omitted This to my mind, is the great gulf that separates the methods under dispute and makes the great difference in the results of different surgeons. Mr Watson Cheyne must have seen many cases with surgeons where this principle was omitted, to the patient's detriment, but where antiseptics were used. As I conceive it and as I practise it the preparation of the patient is of the utmost importance. First, the patient has a bath and the part to be operated upon and the surrounding area are prepared in the following manner washed with warm water and soap—not for a few minutes only but thoroughly well washed—using for the purpose a large piece of sterilised gauze No nail brush is required unless it has been well boiled in order to soften its fibres and so prevent abrasion of the skin. At this time the part is shaved, then rubbed thoroughly with turpentine, dried, and finally rubbed freely with methylated spirit. Thereafter gauze wrung out of 1 in 40 lot. ac. carbol. covering a wide area, covered with gutta percha tissue and left on until the morning On the operating table the same proceeding is gone through again Hands washed in running water before and after this second cleaning soaked in 1 in 3000 hyd. biniodide solution. Dry sterile towels surround the area to be operated upon and no further antiseptic is required. The rest of the operation is carried out without the use of any chemical , only sterile saline solution is used for the wound and perfect hæmostasis is aimed at , the wound is closed with or without drainage, as the condition warrants this, but mostly without. A basin of 1 in 3000 or 1 in 4000 hydr biniodide is placed near the operator and one for the chief assistant for dipping the hands into during the operation and frequently changed. In many case of hernia and abdominal explorations drainage is the exception, the parts being dried and sealed at the end of the operation by collodion and gauze. Large pads of plain sterile gauze are placed upon the wound, and over all a pad made of Hartmann's wood wool wadding, inclosed in gauze, is firmly placed. Sterilised gauze bandages cover all and primary union is the rule. Since adopting this routine I find house surgeon and nurses to be much more careful and less liable simply to dip their hands in antiseptics only Surely no surgeon would permit the use of an instrument that had fallen on the floor Nurses become enthusiasts. Mr Watson Cheyne's description of the nurse cutting up medicated cotton in squares and placing them in unsterilised towels is no part of a well planned aseptic operation. Gauze cut in definite sizes *before* sterilisation, all frayed edges being infolded and doubled so that no free threads are admissible and then sterilised, is what is done in a well planned system , of these first, a size for ordinary mops , secondly a larger for other purposes , and thirdly, a still larger size for abdominal use I have seen what Mr Watson Cheyne describes in an antiseptic theatre, not an aseptic one. But this was on Mr Watson Cheyne's side of the border In the same hospital, which is conducted on purely antiseptic lines, I saw a case being brought in for operation for abdominal tumour The abdomen had never been prepared at all and the house surgeon started with his nail brush and strong perchloride and scrubbed the abdomen most vigorously If that house surgeon had had a few lessons in aseptic methods I venture to say that he would have taken more pains to prepare his case the evening before and have shown a little consideration for the life that was undoubtedly placed in danger But this is where the blind faith in antiseptics comes in. Probably the case did well, and the same procedure may again be adopted, with disastrous results "But antiseptics were used "

Again, in a London hospital where antiseptics are the rule, I saw the assistant surgeon inspect his cases with the dressers The young gentlemen never removed their outdoor coats, never pulled up their cuffs or removed their rings but simply dipped their hands in carbolic lotion and gave them a rinse. Will such a so-called washing remove the gross dirt of London smoke? The surgeon only removed his coat when about to do the first dressing of the patient. What was his procedure? He drew up his cuffs, washed his hands casually in the ward basin with soap, rinsed them in carbolic lotion, and, with a "Pardon me," tapped a student who was in his way on the shoulder and straightway proceeded to dress his wound Instruments should always be boiled in strong soda solution for an hour and all towels used to surround the area to be operated upon should be boiled and thereafter dried and sterilised. In using them dry instead of wet I think it an advantage The wet towel, if applied hot at first, soon becomes cold and unpleasant and in a measure contributes to increase shock. In view of the fact that "organisms floating in the air are essentially non pathogenic," I have gradually given up the immersion of instruments during operation. They are removed from the steriliser and placed in the instrument tray, which has a sterilised towel placed in it and one over it, and then only raised when about to begin All soiled instruments are placed in a basin of boiled water and cleaned and replaced in the towel after use

General precautions —Here it is the duty of the surgeon to devote "extreme attention to the avoidance of any possible contamination," and I do not think antiseptics should be encouraged in this part of the work if it will encourage surgeons to devote less attention. Sponges I have not seen used for some years as the great difficulty is undoubtedly in completely sterilising them. Gauze, as I have described, cut in definite sizes and infolded and sterilised, is infinitely safer I have had difficulty with imperfectly sterilised catgut but not for some time. It is now prepared by Lockwood's method. Gut for ligature and silkworm gut for suture, and silk and celluloid thread, all well boiled before use, for pedicles and buried sutures have proved satisfactory, but undoubtedly gut is difficult to make aseptic. Gauze will never replace drainage tubes, but it is better to have a gauze packing in an abscess cavity than simply to open and to put in a tube. Such a case should be well opened and dried out with gauze, all débris removed, and then packed with gauze. This is better surgery than simply opening and putting in a tube. Better still is to open freely every recess of the abscess, to wash with saline, or saline and peroxide of hydrogen 5 per cent, and to dry, and then to touch up the interior with pure carbolic acid and to fill the whole wound with methylated spirit, dry now thoroughly with gauze and pack for 48 hours, remove, wash around with spirit, dry, and close. This is the most effective method I have yet come across for tuberculous abscess The advantage Mr Watson Cheyne claims for medicated dressings is a further argument in favour of strict asepsis and attention to detail. It ought to be taught that whenever a dressing shows the least suspicion of staining it should be immediately covered by a fresh pad or the dressing changed—knowing that, if this is neglected, the risk of sepsis is too great. On the other hand, surely Mr Watson Cheyne does not teach that if the dressing contain an antiseptic the dressing need not be changed, "nor does the sepsis spread back to the wound." That "pus means sepsis" should be accepted as a good working maxim. There are a few further details on aseptic methods which Mr Watson Cheyne has omitted. I would first mention the prominent part that methylated spirit plays in the subsequent dressing of a wound, and the use of rubber gloves, especially in dealing with septic cases, as a protection to the surgeon's hands and in abdominal operations. Finally, it is well known that sterile saline solution is largely used in aseptic surgery for its unirritating qualities. I experimented with baths of lot. ac. carbol. 1 in 100, lot. hyd. perchlor 1 in 2000, and lot. boric and saline in normal solution, immersing crushed hands and ulcers in them. The saline I found to cause the most rapid granulation and cicatrisation of the wound. Aprons and gowns are essential and need not be discussed. The nurse's position at an operation should be perfectly defined and her duties detailed. There should be one whose duty it is to sterilise the instruments and dressings—the instrument sister—who occupies this place only, another to hold the *basin* containing the sterile mops for the surgeon—*not to hand them to him*, another to attend to the receiver for soiled mops, dressing &c., and, lastly, one to look after irrigation all to have their sleeves rolled up beyond the elbows and to have their hands and arms well washed and clean. That nurses will take all the trouble required I have found from experience, but they must be taught it and have the example of consistency set them the surgeon not going into his bag and doing a lot of thoughtless things after having sterilised his hands

That the aseptic method can be successfully carried out in private practice I have no doubt as all that is wanted is a kettle of boiled and one of boiling water and plenty of freshly laundried towels. The rest is easy and all a matter of routine, detail and constant watchfulness. The work that Lord Lister began in Glasgow cannot stand still, and it seems to me that the great benefits that were commenced by him then are finding their logical conclusion and perfection in the very attention to detail and "trouble" he then advocated and practised and are more certainly likely to be accomplished by the steam sterilisation of dressings and instruments and the strict attention to aseptic detail instead of taking one's chance of the medicated dressings being sufficient to kill every organism that may come their way

I am, Sirs, yours faithfully

JAMES LAURIE, M.B., C M Glasg

Greenock, Feb. 13th 1903.

POLYMASTISM AND POLYPARITY

To the Editors of THE LANCET

SIRS,—As the subject of multiple pregnancies is under discussion in your columns, it occurs to me that it may interest your readers to have their attention called to certain relations between polyparity and polymastism which have not hitherto been noticed. Both these anomalies may, I think, be ascribed to reversion. As I G St Hilaire has remarked "Un individu remarquable par des formes anomales, tombe presque toujours par cela même dans les formes normales d'un autre âge, d'un autre sexe, ou d'une autre espèce." It is under the last of these headings that the anomalies I am considering may be classed.

Among mammalia numerous mammæ in two parallel series are the rule, and for only a single pair to be found—as in mankind—is most exceptional. Now there is a certain relation between the number of mammæ met with in the mature female and the number of young brought forth at a birth, the former being, as a rule, twice as numerous as the latter It accords with this, that polyparity is the rule among mammalia and that the human uniparity is exceptional It is a curious fact that in early embryonic life even human beings have multiple mammary rudiments—arranged just like the mammæ of most adult mammals—although all but a single pair of them, as a rule, subsequently abort As the individual development is generally regarded by biologists as a kind of epitome of that of the race, it may be concluded from this and from other considerations, that human polymastism is a reversion to a primitive condition in which many glands were developed and many young were brought forth at a birth, as is now the case with most mammalia. The transition from polymastism to bimastism may be seen going on in lemurs, whose inguinal and abdominal mammæ are disappearing, so that only one or two pairs of pectoral mammæ are now well developed, and this change has been correlated with diminution in the number of young brought forth at a birth.

Thus it seems certain that the reduction of the primitively multiple human mammæ to a single pair has been brought about in consequence of the change from polyparity to uniparity Other changes consequent on this diminished fertility have been the evolution of the single (unilocular) human uterus from a primitively double form. Some biologists believe that the origin of menstruation may also be traced to this diminished fertility—at any rate, non menstruating mammals are far more prolific than menstruating ones In this connexion it may be mentioned, as Ballantyne and others have pointed out, that the ovaries of very prolific polyparous women, in whom twins are common, are generally of the fœtal type, especially in respect to the immense number of ovisacs they contain.

The question has often been asked whether polymastic women are more liable than others to beget more than a single child at a birth? To this it may be answered that of 70 polymastic women in Leichtenstern's list three had given birth to twins, or 4·3 per cent., whereas the average proportion of twins among British women is only about 1 per cent. In a remarkable case of hereditary polymastism recorded by Marie this anomaly was concomitant with frequent twin-births and excessive prolificacy for several generations. Viewing the matter in this light, let us seek an answer to the question, What is the greatest number of children a woman may bring forth at a single birth? As I have pointed out in my monograph on "Diseases of the Breast," there are good reasons for believing that the human *atavus* had at least seven pairs or mammæ on the ventral aspect of the trunk, of which the present normal pair alone survive. If, therefore, we may answer our query by an appeal to this indication, it would appear that as many as 14 children might possibly be brought forth at a birth. I should not care to deny offhand the absolute impossibility of such an occurrence. Among the ancients Pliny says that as many as 12 at a birth had been noted, and others even 15, but Aristotle would not admit the possibility of more than five. In comparatively modern times, however, apparently well authenticated instances of eight at a birth, seven at a birth, and six at a birth, have been reported. Altogether, it seems desirable to keep an open mind as to the maximum possibility

I am, Sirs, yours faithfully,

Clifton, Bristol Feb 10th, 1903. W ROGER WILLIAMS.

THE RISE OF BLOOD PRESSURE IN LATER LIFE

To the Editors of THE LANCET

SIRS,—If the meeting at which Professor T Clifford Allbutt read his interesting paper on the Rise of Blood Pressure in Later Life was not very numerously attended nor his views then very fully discussed, it cannot be said that the rostrum of your columns has not since then been sufficiently and efficiently occupied by those taking an interest in the subject. The peripheral factors in the production and maintenance of increased blood pressure as life advances have been fully dealt with, although the situation and mechanism of the process have been the subject of divergent or different views for the opinions expressed differ rather than diverge While Sir William H Broadbent and Sir R Douglas Powell have stood stoutly by the theory of capillary resistance Dr Harry Campbell, sustained by the important dead house pathology of Dr William Russell, sees in a bespasmed arteriole the efficient cause of the ultimately persistent process—in the hypertonus of Dr Russell the cause of the arterio-sclerosis of later life We must all feel grateful to Professor Allbutt for having mooted a subject in the felicitous manner so peculiarly his own which has elicited so much fact and so much hypothesis It is not because I can add much of moment to what has already been said that I venture to crave your permission to occupy the momentarily vacated tribune of your journal, but because one or two points which my own study has impressed upon me have not so far been fully brought out in the discussion These are not contrary, I think, to the spirit of Professor Allbutt's argument. In discussing the subject of the rise of blood pressure in later life, it appears to me that the cardio vascular changes secondary to renal disease should be excluded from consideration, except in so far as cardiac failure may induce circulatory renal disturbance, and the diagnosis of these distinct states is not a difficult matter Excluding, then, cardio-vascular change secondary to kidney disease, we find as life advances a hyperplasia of the intima of the vessels and of the interstitial tissue of the heart, with some hypertrophy of the muscular elements in both these situations, a hypertrophy which in the case of the heart ultimately yields to the persistent peripheral obstruction, where the vessel, less active and less organised than the central organ, usually maintains its more sluggish muscular hypertrophy longer The change may or may not as we know, be associated with calcareous deposition. When this occurs, however, the more or less rigid vessels may have an abnormal patency and then the muscular coat, far from being hypertrophied, may, indeed, be atrophied, for it is then not over-exercised but under exercised Such a vessel, when the deposited lime salt is scattered, as it usually is, may, as Sir William Broadbent remarks, be associated with a comparatively soft and compressible pulse, even in old age. The question then is, Does cardio-vascular hypertrophy precede or follow the connective tissue hyperplasia? It is unfortunate that the point cannot be determined during life, and after death both states are found in association unless atrophic muscular degeneration has supervened That both are present in later life, when hypertonus has become persistent—when spasm, if antecedent, has passed into arterio-sclerosis—will not, I suppose, be disputed. It is only, I would suggest, by a more systematic dead house research, with histological examination of the structures involved at all ages and in cases uncomplicated by gross organic disease, that the point can be settled Such an investigation, so far as I am aware, has not yet been made and our argument must of needs, therefore, at present be largely hypothetical So far as I *may with diffidence express an opinion, I am inclined to* believe that if muscular hypertrophy be primarily due to active and sustained hypertonus it is soon increased by having to deal with the more persistent inelasticity of connective tissue hyperplasia and that such connective tissue increase is, therefore, an active cause in heart and vessels of difficulty in propelling and conducting the circulation as life advances and provocative of the compensatory changes necessary to deal with it This, then is one point which I desired to emphasise. The other is, that, in my belief, the study of the peripheral physiology and pathology of the vessels has distracted attention in a measure from senile changes in the heart capable of being generated by its own activity, apart from the abnormal labour thrown upon it by peripheral ob
that is, that the nervous, muscular, and hæmic factors

ALEXAN

Upper Berkeley street, W , Feb 13th, 1903

To the Editors of THE LANCET

SIRS,—I have read the correspondence on Mr Blood Pressure in Later Life which has already a di THE LANCET with much interest, and venture to ed permission to make a few remarks with special re e the relationship of general arterial hypertonus to t g pressure. This relationship is undoubtedly a very e one, and personally I am quite satisfied that when t , of the radial artery are tightly contracted the within may be either considerably increased or lowered

There is no doubt that the arteries respond very pre to the action of toxic substances circulating in the and in such circumstances their calibre is diminis This may be called *toxic* arterial *contraction or* hyperto and the condition is present in all cases of auto-intoxicat whether arising from poisons which are absorbed from alimentary canal or due to certain chemical chan occurring in the tissues as a result of abnormal metaboli Anyone may suffer from this kind of hypertonus and dur the time that the arteriole contraction is present I beli that the blood pressure is almost invariably raised in larger arteries. Marked diuresis for several hours is ofte striking feature of this transient toxæmia, and when toxins are eliminated the calibre of the radial artery is fou to be enlarged. Dr Harry Campbell's explanation of t greatly increased secretion of urine in such cases—that wh the systemic arterioles are contracted those of the renal fi are dilated—may be correct but it does not always appl Thus in the grave auto-intoxications of pregnancy sometimes culminate in eclampsia hypertonus is an and persistent feature and is accompanied by a marked ri in the blood pressure. When such symptoms are the secretion of urine is notably diminished and as tonus and increased pressure become more pronounced urine may be suppressed altogether In myxœdema an cretinism, which are typical auto intoxications, hypert is always present, and the increased blood pressure in diseases is associated with a lessened urinary secretion

The point which I wish to emphasise, however, is *toxic hypertonus is seldom present* for any length of tim without some augmentation of the blood pressure, and believe that the explanation of this is to be found in the fac that in these cases the obstruction to the flow of blood not only in the arterioles but also in the capillaries *Arteriole contraction alone* as it is observed in cases *non toxic* hypertonus, is certainly very often by any increase in the blood pressure, and the imp of the capillaries in the area of peripheral resistance m be regarded as a factor of primary importance when th pressure is considerably raised. It is well recognised that the capillaries are much more sensitive to the action of toxins than the arterioles

Non toxic hypertonus is a prominent feature in certain diseases of the nervous system and may also be induced by severe abdominal pain, tympanites, or any form of profound shock. The tonic contraction of the arteries is often very striking and this kind of hypertonus is typically present in some cases of tuberculous meningitis during the irritative stage. Sometimes even in young children, the radial artery feels like a piece of whipcord and I have always found the blood pressure extremely low When as a result of peritonitis or shock, hypertonus is present (the "wiry" pulse), the pressure is also frequently abnormally low, and remedies which produce a relaxation of the vessels lead to a raising of the blood pressure In such cases there is a general arteriole contraction, due either to direct irritation of the vaso-motor centre (meningitis cerebral tumour, &c), or indirectly produced by some disturbance of the abdominal sympathetic system. There is no unusual obstruction in the capillaries. In some cases of marked arterio-sclerosis in old people, where the lumen of the radial artery was greatly diminished, I have found the blood pressure exceedingly low, but there was no reason to suppose that the capillary area was unduly obstructed. Similarly in old syphilitic vessels with nearly obliterated lumina, the pressure registered was sometimes very low

In conclusion the following points may be stated (1) in cases of *toxic* hypertonus the arterial pressure is, as a rule, considerably raised, and this is mainly brought about by contraction of the capillaries, which, like the arterioles, participate in the area of increased peripheral resistance, (2) in *non-toxic* hypertonus the blood pressure as registered in the radial artery commonly remains unaltered or may be greatly diminished. The obstruction to the flow of blood is then chiefly due to arteriole contraction, the capillary field is not implicated. I am, Sirs, yours faithfully,

Edinburgh Feb 16th, 1903. H. OLIPHANT NICHOLSON

THE VALUE OF CHLORETONE IN SEA-SICKNESS

To the Editors of THE LANCET.

SIRS,—When travelling as surgeon of one of the Union Castle steamers I was much struck with the value of chloretone' (a product of chloroform and acetone prepared by Parke, Davis, and Co) in some cases of aggravated sea sickness. Beginning with a dose of ten grains, I administered five grains at intervals of three hours until the stomach nausea and head congestion were relieved, and the patient sank into a natural and gentle sleep. In every case on waking there was a natural appetite for food and fruit, biscuit, soup, beef tea, and stimulants were readily retained. By the continued use of the drug in five grain doses at four hour intervals, the symptoms in the worst affected were controlled for several days of very rough weather and the less affected cases were rendered quite good travellers. The most noticeable clinical feature of its action was the rapid effect produced on the pulse, converting the quick, tense beat of sea sickness into the fuller and more regular one of health a quarter of an hour after being swallowed. The relief of headache without any heart depression whatever is a very strong point in favour of its use in persons with any organic disease of the heart or kidneys, and as a pure stimulating hypnotic without any bad after effects it deserves a foremost place.—I am, Sirs, yours faithfully,

L WHEELER, M B., B Ch. R U I

Junior Conservative Club, London, Feb. 22nd, 1903.

A CASE OF HERNIA INTO THE FOSSA DUODENO-JEJUNALIS

To the Editors of THE LANCET

SIRS,—Mr B G A Moynihan in THE LANCET of Feb 7th, p 393, has thought it necessary to take notice of my record of a Case of Hernia into the Fossa Duodeno-jejunalis which appeared in THE LANCET of Jan. 24th, p 236 This case was carefully dissected and I made drawings of the relations of the parts round. The free margin of the orifice was *formed* by a thick fibrous mass in which was found the left colic artery besides this the inferior mesenteric artery, where it came off the aorta, could be said to form the lower *cornu* of the opening The inferior mesenteric vein was distant to the left from this margin about half an inch It did *not* as Mr Moynihan presumes, occupy the "neck" of the sac, but ran almost vertically at the above-mentioned distance For this reason is it not probable that the case was properly named? Mr Moynihan says that the condition of the fossa to be properly appreciated must be studied in the fœtus or young child I have it on the authority of a most careful observer and competent embryologist (possibly the most competent in the country), whose observations will probably soon appear, that out of a series of 47 fœtuses in only one was there the slightest suspicion of a fossa of any kind in the neighbourhood of the duodenum so that the nine fossæ so exactly described by Mr Moynihan are probably formed later in life.

I am, Sirs, yours faithfully,

Aberdeen, Feb 16th 1903. C T ANDREW

ANEURYSM OF THE ASCENDING AORTA.

To the Editors of THE LANCET.

SIRS,—I have read Dr A C Jordan's paper in THE LANCET of Feb 21st, p 515, on aneurysm of the ascending aorta in a small boy with great interest One cannot help regretting, however, that the chest was not examined during life with the x rays True, there were no physical signs calling special attention to the chest, but I venture to think that had the chest been so examined much light might have been thrown on the case The aneurysm, judging from Figs. 1 and 2, was quite large enough to have been so detected. The only element of doubt in the diagnosis would have been between an aneurysm and enlarged bronchial glands, the latter condition being, of course, much more likely in a child six years of age, but the continuity of the shadow with that of the heart and aorta, and more especially the pulsation of the sac, would, I think, have left no doubt about the diagnosis. I venture to think that the day will come when a patient will be examined with the x ray screen as a matter of routine in the same way as he is now examined with the stethoscope, and I think the sooner that day comes the better I, for my part, can only say that I have found x-ray examination of the chest in my out-patient room and in private practice of very great value. I am, Sirs, yours faithfully,

Harley-street W Feb 21st 1903 HUGH WALSHAM.

THE CULTIVATION OF ANAEROBIC BACTERIA

To the Editors of THE LANCET

SIRS,—Mr H S Fremlin draws attention in a note on p. 518 of THE LANCET of Feb. 21st to a method of cultivating anaerobic bacteria in plate, of which a detailed account is promised in the forthcoming report of the medical officer of the Local Government Board. Will you allow me to draw Mr Fremlin s attention to the fact that a method based on identical principles and manipulations has already been described by myself in the report of the medical officer of the Local Government Board for 1897–98 on p. 219

I am, Sirs, yours faithfully,

St Bartholomew's Hospital, Feb. 21st 1903. E KLEIN

APPENDICITIS IN ITS ACUTEST FORMS A CORRECTION

To the Editors of THE LANCET.

SIRS,—Will you kindly grant me space to correct an error and one omission in my paper upon appendicitis? The error appears in connexion with the numbers and the mortality of the cases of typhlitis and peritonitis occurring in St. Bartholomew's Hospital in the years 1882 to 1884 In all 79 cases were registered with a mortality of 23—not 41, as stated on p. 503 of THE LANCET of Feb 21st

The omission is the want of any reference to a note in the *British Medical Journal* of April 5th, 1892, p 54 to which I am indebted for valuable information and through which my attention was first drawn to the work of Battey regarding the occurrence of pelvic peritonitis in the male sex.

I am, Sir, yours faithfully

Cannes, Feb. 23rd, 1903. J A. MACDOUGALL.

A QUESTION IN INEBRIETY

To the Editors of THE LANCET

SIRS,—In THE LANCET of Feb 21st, p 552, Mr. C. E Macnamara states his opinion that the inebriate is possessed of a strong will and asks the opinions of your readers. If

Mr Macnamara opens "The Present Evolution of Man," p 347, or "Alcoholism A Study in Heredity," p 83, he will find that if his opinion is heterodox it is certainly not new

Mr Macnamara seems to class "will" as an independent faculty of the mind Is this so? Buckle, in his "History of Civilisation," vol. i., chap i., gives good reasons for believing that it is not and for believing that the actions of men are governed by fixed laws Herbert Spencer, as quoted by Dr Archdall Reid, states that "the will of man is trammelled by his desires," and Dr Reid puts the case clearly and accurately when he says "It is a simple truth that the will of man, as of all animate creatures, is exercised, *as a rule*, to gratify, not to cross, his desires"

I am, Sirs, yours faithfully,
C R. NIVEN

(Concluded from p 555)

Threat of the Swansea Friendly Societies to create a Medical Institute of their own —Statistics as to Medical Remuneration.—Success of the Swansea Practitioners

AT Swansea, as at Chesterfield and in many other places, the one great threat of the friendly societies is that they will amalgamate and form a medical institute or dispensary, employing exclusively for their own purposes one medical officer or more. This proposal is all the more menacing because its practicability has been demonstrated. Such institutions have already been created and exist in several towns What little advantage can be derived from club or contract work by the local practitioners is lost when such an institution is established, on the other hand, the attendant evils are accentuated A local practitioner who besides attending private patients is also medical officer to a friendly society can, if he is bold enough, protest against any case of flagrant abuse and he may also hope to acquire popularity and thus to increase the number of his private patients But the managers of a medical institute import a practitioner who is a stranger to the town they lodge him in their own house, and the agreement contains not only a clause that he must have no private patients but it is sometimes also stipulated that on leaving the institute he must not establish himself in practice in the neighbourhood. These are rules devised to make the medical officer an absolute servant and to deprive him of the slightest shred of independence. He is likely to lose the respect of the members of his profession and whatever name and standing he may have possessed. All this makes him still more dependent upon his employers and he will probably be careful to give every satisfaction to the members of the managing committee of the institute to whom he has sold his freedom and his services. But it does not follow that all the members of the friendly societies by thus enslaving their medical officer insure for themselves really efficient medical attendance. A slave may be whipped till he carries a certain load and accomplishes a certain amount of physical work. But this is not the way to develop qualities which are essential for a sound medical practitioner The efficaciousness of medical treatment depends on the sympathy and interest which the medical attendant feels in his patient, or else the medical attendant should have a motive to spur him on in his efforts—an interest in his science if not in his patient and some possibility of progress and reward to look forward to But these medical institutes nip all such aspirations in the bud. There is nothing to work for, there is only the dead level of a modest salary, little or no prospect of an increase, no chance whatever of distinction, no possibility of professional advancement, no hope of fortune or fame, in a word, there is no future at all Yet it is by offering such conditions as these that the members of these friendly societies ingenuously believe that they are going to secure for themselves better medical attendance.

The friendly societies of Swansea have issued an appeal and in the lengthy circular which they have published they not only denounce the club medical officers for their neglect but they propose to form an association for the purpose of establishing a dispensary This institution, they say, would be "entirely controlled by the friendly societies" and worked for their own benefit. There is no question here of any benefit for the medical profession, on the contrary, the only people who are to derive any advantage are the members of the friendly societies The members, their wives, and children are all to be insured "efficient medical attendance and the best of medicines," and the duly qualified practitioners who are to do all this "will not be allowed to take on any private practice, but will devote their whole time to the service of the association" The members will buy their own drugs and establish a dispensary under the direction of their medical officer The members are to live within three miles of this centre and to pay 8*s* a year for themselves and their whole families. They publish a good array of statistics to prove that the results obtained by 42 similar institutions indicate that 8*s* per member will suffice. For instance, we are told that there are 15 associations with from 1000 to 2000 adult members each, or in all a total membership of 33 700, and that they employ 22 medical officers and five dispensers. The average annual cost per member works out at 7*s* 1 73*d*, which is subdivided at 4*s* 6 13*d* for the medical officers and dispensers, 3 28*d* for conveyances, 9 91*d*. for drugs and appliances, 7 99*d* for house bills, 3 07*d* for offices and committees, and 7 35*d* for sundries. But these and other similar figures do not explain what is meant by adult membership It is the children who give the greatest trouble. These fifteen societies, or amalgamations of societies, give the largest average sum to their medical officers Next on the list are eight associations with from 2000 3000 members each that give but 3*s* 8 84*d*, 12 assc tions of from 3000 to 4000 members each that 3*s*. 2 44*d*, four associations of from 4000 to 5000 m each that give 3*s* 3 92*d*, three associations of from 5000 to 6000 members each that give 2*s* 06*d*, and association of from 6000 to 7000 members which 2*s* 5 78*d* per member per annum to their med officers and dispensers Deducting the salary of dispenser we find here medical men receiving less than per member If we make an average of the various allotted to the medical officers and dispensers by these different categories of associations, the result is a under 3*s* 3*d* per member per annum. Dr T D has reckoned that at 4*s* 4*d* per annum the medical received about 2*s* 6*d* for every week's actual attendance patients, but the above figures make it only 1*s* 10¼*d* week, or 3¼*d* per day So here we have a total of 122, members of friendly societies who, according to the fi they themselves publish, are actually receiving the services medical officers and dispensers for the munificent remuneration of 3¼*d* per day's attendance The officer has to see the patient and to prescribe for him the dispenser has to mix the drugs, and then, the dispenser and the medical done this, the dispenser and the medical have 3¼*d* to share between them as the reward their work. This is the sort of institution which it was pro posed to establish in Swansea so as to render it quite that in future the members of the friendly societies be properly attended when ill. They actually that this arrangement would be an improvement on present state of affairs. They did not seem to stand that a medical practitioner may see a patient for 3¼*d* or less, or for nothing if by so doing he is acquiring ence and raising himself in his profession, but proposed, on the contrary, conditions that would their medical officers and probably cause them to be cised by their fellow members of the profession. What of practitioner could the members of the friendly expect to get under such conditions? Not men who for the honour of their profession, but men who for reason or other have abandoned all hope and are content accept a fixed sum that will guarantee them against want.

The argument raised at Swansea was that the club officers sometimes neglected their patients, therefore friendly societies must amalgamate and start a dispensary medical institute of their own To this the members of medical profession replied that if the patients were c ally neglected it was because a good deal of abuse vailed and the payments made were absurdly inadequate Thereupon some of the most active leaders of friendly societies rejoined that in these circumstance best thing to do was to create a federation of societies so as to pay their medical officers even less than they had been in the habit of paying The application to economics of the old maxim that "like cures like" did not, however, find favour so readily as was expected Besides, though there was every prospect of paying the medical officers of the proposed dispensary less than is actually given for medical attendance, the members themselves would have to pay well nigh the same sum The Swansea and District Medical Practitioners' Association promptly agreed that it would try to meet the members by limiting itself to a very moderate demand. There is a sort of tacit agreement or feeling that the minimum pay for contract or club work shall be 1*d*. per week for adults and ½*d* per week for children. There is also a very strong feeling that for the better class of artisans, who to a large extent belong to the friendly societies, the families should not be allowed to join such organisations. However, Swansea was so much behind other centres in these matters that the question of excluding families had to be set aside for the moment. It is not practicable to pass at once from the worst to the best conditions, it was therefore felt that the progress must be gradual The average payment was said to be 6*s* 6*d* per annum per family but a strong point was made of the fact that those members who had no families paid the same amount. The value of this consideration naturally depends upon the proportion of unmarried members and it was maintained that only two-thirds of the members were married. The Medical Practitioners' Association on the strength of this statement replied that its members would consent to attend the members of the friendly societies and their families for an all round payment of 8*s* 8*d* per annum. This means that the married members would pay for themselves and their wives only at the rate of 1*d* each per week It also means that the unmarried members would pay 1*d* per week for themselves and 1*d* per week for the children of their married co members. In this respect the bachelors of Swansea occupy a unique position and considering their generosity towards their married friends it is not surprising if the medical profession followed this example and also showed some indulgence towards large families. At a halfpenny per week each bachelor pays for two children and as there are twice as many married couples as there are bachelors each couple has one of their children paid for by the bachelors All the children over and above the average of one child per couple are not paid for at all. Such are the conditions which the members of the profession declared that they were willing to accept The Medical Practitioners Association summarised the matter in the following terse manner —

> Two alternatives present themselves to you—either to accept the services of the medical men now in Swansea who are prepared to attend you for 8*s* 8*d*. or throw in your lot with the proposed medical aid association who *say* they will ask 8*s* but can give no guarantee. Are you prepared to cut yourselves off from the services and goodwill of every medical man now practising in Swansea for the sake of a possible saving of eight pennies a year?

After some hesitation the answer was recently given. The friendly societies have abandoned their scheme of creating a medical institution for providing their members with medical aid and drugs and have accepted the terms set forth by the Swansea and District Medical Practitioners Association. Though these conditions do not amount to the minimum of a penny per week per adult and a halfpenny per child still they are a great improvement on the old annual average of 6*s*. 6*d* per member, which sum included his family if he were married. But the medical practitioners have obtained another and more solid advantage From the very beginning higher subscriptions have been claimed by the surgeons attached to particular works It is argued that the surgery must be close to the works or factory and that such districts are not suitable for private practice. Then if the works are stopped in consequence of a strike or any other cause the medical officer has to continue to attend his patients though he gets no pay at all Again, though he has to have *his* surgery near the works the workmen themselves often live at considerable distances and not all in the same direction. This causes much loss of time when they have to be seen in their own homes. Therefore the Medical Practitioners Association declares that though it would accept 8*s* 8*d* from the members of the friendly societies it would require 13*s*. per annum per member from the medical aid organisations connected with the copper tin steel tubing, and other works. The majority have now consented to these terms, though at three large works these new conditions have not yet been conceded

Such, then, is the present state of affairs and it will be seen that some solid advantages have been gained in a very short time Thus once more has the use of organisation been demonstrated The situation is still unsatisfactory in many respects and there yet remains a good deal of abuse. Tradesmen and comparatively rich men belong to the friendly societies and the need of a wage limit is felt keenly at Swansea as well as elsewhere. As at Lincoln so at Swansea, one of the principal men in the town was a member of a friendly society and paid only 4*s*. 6*d* a year for his medical attendance. The society to which he belonged had 733 members and paid its medical officers £170 for attending them and their families. It has been calculated that at such rates of payment if the whole population of Swansea was thus enrolled the medical practice for the town would not yield more than £120 per annum to each of the practitioners established in the town, and with this £120 he would not only have to keep himself and his family but he would have to dispense and to supply drugs to all his patients, to pay rates and taxes and to keep open a surgery for the use of his patients

It will be seen, therefore, that a wage limit is absolutely necessary, indeed, this is more important than the question of the amount paid in subscriptions. It would be far better to attend the poor for nothing so long as those who can pay do not avoid doing so As it is all these discussions have had another good effect Several persons have given up subscribing to clubs and the tendency is in the case of many persons again to seek private medical advice. One local practitioner had found it to pay better to charge poor people 5*s* a week when they were ill and nothing when well. With this system he had not had 4 per cent. of bad debts This, again, raises the question of what should be the minimum fee in private practice, a problem which will soon have to be solved by the young society which the medical practitioners of Swansea have recently created. It is to be hoped that its future endeavours will continue to meet with the success that has rewarded its first efforts.

MANCHESTER

(FROM OUR OWN CORRESPONDENT.)

The Spread of Small-pox

DURING the week ending Feb 7th 36 cases, and during that which ended on Feb 14th 19 cases, of small-pox were removed to the Clayton Hospital. In the first week a case was overlooked that occurred in a common lodging house. Dr J Niven believes that from this one 17 cases were infected, nine at the lodging house, three at private houses four at the workshop which the man continued to attend while ill, and also that of a publican in the neighbourhood. It is, of course, difficult to trace all those who may have been infected by patients, but this has been done as much as possible and many 'contacts' have been revaccinated In some cases, however, difficulties have arisen. The head of a private household from which three people were removed to hospital refused to allow his family to be revaccinated These anti vaccinationists are not merely harmless cranks or nuisances but are a serious danger to the community and it becomes a matter for consideration how best to guard against it. The principle of liberty for the subject to endanger his friends and neighbours is too sacred a fetish to be mentioned irreverently but a little compulsion in favour of vaccination is better than small pox. Then, too, through the shifting habits of a large section of the population many children remain unvaccinated. And it must be confessed that the medical profession is not free from responsibility for a part at all events, of the unpopularity of vaccination. While small pox was out of sight and therefore out of mind mothers appealed to the medical attendant to cause their infants as little suffering as possible. The medical attendant, in the tenderness of his heart and feeling perhaps some scepticism as to small pox ever again becoming an appreciable danger, too often yielded so far as to make vaccination a very feeble protection. The statistics of the small pox hospital showed this long ago It may be that the suffering caused by this most loathsome disease both to patients and friends, that the loss of many lives, some of them valuable and all human, and that the expenditure of tens of thousands or hundreds of thousands of pounds in battling with a foe which ought not to, and could not, have obtained a footing in our midst if we had been properly prepared, may lead to wiser views and more common-sense action. Against this hope, however, it must be remembered that a wise man said, "Though thou shouldest bray a fool in a mortar yet will not his foolishness depart from him." Two more cases were reported to the Manchester authorities on Feb 22nd and one on the 23rd, and two more were discovered on the 23rd in Salford. There are about 90 patients in the Clayton Hospital at present.

Bury District Small-pox Hospital

The small pox hospital at Ainsworth, erected by the Radcliffe, Ramsbottom, Whitefield, and Bury hospital committee, was opened yesterday It is to accommodate 16 or 20 patients if necessary The nurses will occupy two cottages, which have been thoroughly renovated. But what a pity it is that these hospitals have been rendered necessary by our own weakness.

Oldham War Fund

The balance of the Oldham war fund was on Feb 23rd at a public meeting of the subscribers disposed of as follows £10 to the honorary secretary as a recognition of his services, £350 to the Soldiers' and Sailors' Society for the provision of a home for an aged soldier or sailor in Oldham, and £1009 8*s* 11*d* to the Queen's Memorial Fund for the extension of the Oldham Infirmary

The Triple Disruption

In accordance with general expectation Liverpool and Manchester are to have their separate and distinct universities. This decision of the committee of the Privy Council falls in with the known desires of the two cities but is opposed to the wishes of the Yorkshire College. Indeed, it is questionable if Manchester would have moved in the matter but for the irrestrainable, not perhaps unjustifiable, ambition of Liverpool. Yorkshire for the present seems to be rather left out in the cold, but if Lancashire can support two universities there is no doubt that Yorkshire is quite able to support one. But whether Yorkshire's university shall consist of the Leeds College only or shall embrace the Sheffield University College and possibly others as yet non existent remains to be seen There is disappointment, not unnatural in Sheffield that the Privy Council has not associated it with Leeds now that one of the strongest objections to the admission of the Sheffield College to the Victoria University in 1897—i.e., the inadequacy of the buildings—is in a fair way of being remedied It seems that for the completion of the scheme for new buildings the sum of £20,000 only is required and it is hoped that this sum may be raised within the city in a very short time. Possibly in the draft charter for the incorporation of a university in Yorkshire which the authorities of the Yorkshire College are to have the opportunity of submitting the claims of Sheffield may be set forth These changes and developments will in the future have an important bearing on medical as well as on general education in the north of England Some fear that interests may be too much localised, that wide views may become narrowed, and that three provincial universities may be in danger of setting up three varieties of provincialism It is to be hoped that it will not be so, but having cast off its limbs, after the fashion of some other invertebrates, it will be of interest to see what becomes of the fragmentary remains of the Victoria University

The Owens College

Dr Judson S Bury has been appointed clinical lecturer on neurology The council of the College has received a bust, presented by Dr D Lloyd Roberts, of Charles White F R S (1728–1813), one of the founders of the Manchester Royal Infirmary and for nearly 40 years one of its surgeons. Dr H. A G Brooke has presented to the council a bust of Lazzaro Spallanzani (1729–1799), who was professor of logic, mathematics, and Greek at Reggio, of natural history in Modena, and then in Pavia. It is a replica of one placed in honour of Spallanzani in the School of Physiology in the University of Modena. A valuable collection of calculi has been presented to the medical museum by Mr Andrew Boutflower senior surgeon to the Salford Royal Hospital. Mr C F Myers Ward, formerly demonstrator in physiology in the Owens College has accepted the post of lecturer in physiology in Charing Cross Hospital, London Dr G N Stewart, F R.S., another former demonstrator in the same department, has been appointed to the chair of physiology in the University of Chicago

Feb. 24th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Swansea Isolation Hospital

FOR more than 20 years the members of the Swansea corporation have been discussing the desirability of erecting an isolation hospital for the town and time after time it has appeared to be certain that such an institution would be speedily provided. During the past year plans have been prepared, a site has been secured, and a committee has reported favourably upon completing the purchase but at the meeting of the corporation on Feb 18th a resolution was passed by the casting vote of the mayor in favour of abandoning the proposed site The responsibility of finding a fresh site and that without delay, now rests with the mayor and with those who voted with him, for it is little short of a scandal that a county borough having a population approaching 100,000 should be without this most important and necessary line of defence against outbreaks of infectious disease. When small pox was prevalent in the town last year the Swansea tradesmen were very indignant at the publicity which was given to the bare facts concerning the outbreak and were partially successful in suppressing information of the epidemic, if they really desire to attract visitors to the district they will insist upon a suitable hospital being established forthwith

New Asylum for Breconshire and Radnorshire

The new asylum which has been erected at Talgarth for the counties of Brecon and Radnor was formally opened on Feb 18th by Lord Glanusk, chairman of the Breconshire county council, and the first patients will be removed from Abergavenny early in March It is of interest to recall the history of the Monmouthshire asylum which was built at Abergavenny in 1847 for the joint use of the counties of Monmouth, Hereford, Brecon, and Radnor where there was at that time a total population of 360,000 persons. The accommodation then deemed ample was for 210 patients, about equal to one in 1500 of the population. The cost of the building was at the rate of £190 per bed Although additions were from time to time made to the original structure the added accommodation did not keep pace with the increasing population of Monmouthshire, the population of the other counties remaining nearly stationary In 1870, when there was a total population in the four counties of 405,000, the county of Hereford seceded from the combination and erected an asylum near the city of Hereford which with recent additions can accommodate 500 patients, a number equal to one in 240 of the population of the county In 1890 when the three remaining counties had a population of 330,000 persons, Monmouthshire decided to dissolve the partnership with Breconshire and Radnorshire and from the present date the Abergavenny institution, where 1098 patients can be treated will serve only the needs of Monmouthshire until a further reduction is made in the area from which patients are brought upon the completion of the asylum which the Newport corporation contemplates erecting The Talgarth asylum buildings cover about seven acres within an estate of 255 acres An existing house has been converted into a residence for the medical superintendent and the new buildings include six two-storey blocks surrounding an administrative block, a chapel a laundry block, and an isolation hospital The stone used in the construction of the buildings was quarried from the estate and bricks were made on the spot from local clay Of the six blocks, two are for epileptics, two are for recent and acute cases, and two will be used as infirmaries The central dining and recreation hall, which is fitted with a stage, will seat 500 persons The present accommodation is for 350 patients, but the administrative portion is for an additional 150 The buildings are lighted with electric light and the laundry machinery is worked by electromotors Water is obtained from the Enig brook and is conveyed to a storage reservoir with a capacity of 114,000 gallons The roof water is conveyed into an underground tank. The sewage is disposed of on the land The total cost of the asylum will be about £150,000, a sum equal to nearly £430 per bed on the basis of 350 beds, but the amount per bed would be very much reduced in the event of any enlargement being required The combined population of the two counties of Brecon and Radnor at the last census was 83,000, an increase of only

4300 over the previous census and of only 2000 in the last 50 years It is hardly likely, therefore, that any additional accommodation will be necessary for many years. Mr W Ernest Jones has been appointed medical superintendent and Mr A J Hassard assistant superintendent of the asylum.

Bristol Medical Dramatic Club

The twenty sixth annual performances of the Bristol Medical Dramatic Club took place at All Saints Hall, Clifton, on the evenings of Feb 17th, 18th, 19th, 20th, and 21st, when the comedy of *Our Boys* was very successfully presented. The attendance was large and it is hoped that the medical charities in aid of which the performances were given will benefit considerably

Torbay Hospital

The fifty ninth annual meeting of the subscribers to the Torbay Hospital was held on Feb 19th. The medical report stated that 413 in patients had been treated during 1902, an increase of 12 compared with the previous year 869 minor accidents were treated in the out-patient department and 675 persons were treated as out-patients in the ophthalmic department. The financial statement showed that the year closed with an adverse balance of £400 The president (Mr W Kitson) in drawing attention to the need of more financial support for the hospital, alluded to the satisfactory settlement of the difference in connexion with the medical staff of the hospital, and added that the hospital was now doing more work than ever

Feb. 24th.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Association.

A MEETING of the council of this association was held in the Royal College of Surgeons on Feb 18th with the primary object of considering the advisability of holding conferences of representatives from the county branches connected with the association for the purpose of formulating a scheme for reform in the Poor law Medical Service affecting salaries, superannuation, vacation, &c., which would be acceptable to the medical officers throughout Ireland.

The Richmond (Dublin District) Lunatic Asylum.

At a special meeting of the corporation of Dublin the Lord Mayor, in a financial statement, called attention to the enormous increase in the rate in respect of the management and maintenance of lunatic asylums. He said that in 1893 the demand upon the rates for the Richmond Lunatic Asylum after deducting the Government grant was £14 096 For the current year the demand was £47,036, making a difference of £32 940 in the municipal rates of the city He said that it was a very serious charge but that it was due to a large and very costly but essential increase in the buildings for lunatic asylum purposes and to the fact that there had recently been an increase in the number of lunatic patients to be provided for

Medical Students Guide

The Royal College of Surgeons in Ireland has just issued a medical students guide, giving full particulars of how to become a medical man , it commences with the preliminary entrance examinations, giving specimens of previous questions set, and the fees payable for each term. The extrance examinations will be held this year on March 23rd and Sept. 21st. The guide will be forwarded post free on written application to the Registrar Royal College of Surgeons, Dublin.

Belfast Maternity Hospital.

At the 109th annual meeting of the supporters of this charity, which was held on Feb 17th, it was reported that there had been during the year 312 intern patients with only one death, while 251 women had been treated at their own homes. In the extern gynæcological department 538 patients had attended The total ordinary income was £543 0*s* 2*d* , while the expenditure was £701 6*s* 2*d* , but the proceeds of a special bazaar together with donations, brought the institution into a proper financial state at the end of the year The chairman announced that they were on the look-out for a suitable site for their new hospital which they hoped would be in every respect an up to-date one. To the vacancy caused by the resignation of Dr Brice Smyth, Professor J W Byers of Queen's College has been appointed.

Ulster Medical Society

The fifth general meeting of this society was held in the Medical Institute, Belfast, on Feb 19th, Dr S. Agnew (Vice President) being in the chair Dr H. L McKisack showed a patient with Spastic Paraplegia (primary lateral sclerosis) Dr Thomas Houston showed a beautifully mounted specimen of the Head of Tænia Solium and the Body of Tænia Mediocanellata (21 feet 6 inches long) kindly lent by Sir W Whitla. He also showed some Bronchial Casts from a case of Bronchitis under the care of Dr J R. Davison. Dr J McCaw read a paper on a case of Paroxysmal Hæmoglobinuria in a child and showed a patient. Dr Agnew, Mr D Stead, and Dr Houston took part in the discussion Dr J Singleton Darling and Dr McKisack communicated notes of a case of Pericardial Effusion and Dr Robert Boyd, Dr McCaw, and Dr A. Dempsey took part in the discussion Dr A. L Bell (Holywood) was elected a fellow of the society

Queen's College, Belfast

The students' representative council of Queen's College Belfast, has decided to hold a dinner in 'Ye Olde Castle ' restaurant, Belfast, on St Patrick's Day (March 17th) limited to present and past students of the College. Serjeant Dodd, K.C , has kindly consented to preside. It has also been arranged to hold a small fancy fair to raise money needed for the students' union. It is to be held in the McMordie Hall on March 12th, 13th and 14th.

Feb 26th

PARIS

(FROM OUR OWN CORRESPONDENT)

Compulsory Vaccination and Revaccination

IN February, 1902, the French Parliament passed a Bill dealing with public health and one clause of this Bill was concerned with compulsory vaccination and revaccination. It was necessary that an official notice should be issued concerning the application of the provisions of this paragraph and the notice was drawn up after consultation with the Academy of Medicine and the Consultative Committee of Hygiene One year's grace was given before the law came into operation and the Consultative Committee was invited to draw up a scheme of regulations concerning vaccination and revaccination. This scheme was submitted to the Minister of the Interior and he in his turn referred it to the Academy of Medicine on Oct. 20th 1902. The Academy appointed a committee of seven members to examine into the question and on Feb 3rd, 1893 M. Kelsch submitted to the Academy the conclusions of its committee which were agreed to The scheme of the Consultative Committee of Hygiene was eminently bureaucratic , it created a superior vaccine institute charged with the duty of certifying the purity of the vaccine employed in every authorised vaccination centre, whether such centre was official or in private hands The Academy of Medicine, which had already organised a department of its own for gratuitous vaccination, to which it gave a great deal of trouble and care, did not appear to relish the idea of the newly created department which put it (the Academy) on the same plane as any other vaccine establishment. The Academy therefore declared that the superior vaccine institute should be the Academy itself and that the director should be a member of the Academy Further, the Academy gave it to be understood that it would sooner close its vaccine department than accept the control of any other authority It is by no means certain that the ideas of the Academy will prevail against the scheme of the Consultative Committee of Hygiene. The Academy leaves heads of families free to choose their own vaccinator All the same, there are to be official vaccinators appointed who will organise gratuitous vaccination throughout the country at the expense of the local authorities (*conseils généraux*) The annual expenses are estimated at something considerable, but, as M Kelsch pointed out, small pox costs France from ,9,000,000 to 10,000,000 francs per annum. After all, the need for these new regulations does not seem very great. Already proof of vaccination is exacted from all French persons of both sexes at every step in their career There are vaccination centres in plenty and the Academy of Medicine is fully organised to keep up both the supply of lymph and the supply of medical men. Vaccination is obligatory in all schools and gratuitous vaccination is well organised The scheme of the Academy of Medicine concerning vaccination makes it obligatory within the first year of life and revaccination obligatory at the age of 11 years and again at the age of 23 years Calf lymph alone may be used

The Effect of Rays from Radium

At the meeting of the Academy of Sciences held on Feb 16th M Roux, for M Danys, read a paper on the Physiological Effects of the Rays given off by Radium On the skin of a rabbit the rays produced some superficial eschars and these were followed by a marked increase in the growth of the hair A fragment of the metal placed in the peritoneal cavity remained there for four months without causing any trouble M Danys also placed tubes containing radium against the spinal column in mice of varying ages Acute nervous disturbances were at once set up and young animals died in three days Older mice lived for eight days The emanations from radium will not pass through adult bone, but a tube containing radium placed over a trephine hole in the skull of a dog set up hemiplegia after a few hours The rays kill the larvæ of certain butterflies and meal worms, while they retard the development of most microbes.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Is Tuberculosis conveyed by Food ?

Professor von Hansemann, formerly an assistant to the late Professor Virchow and now prosector to the Friedrichshain Hospital, recently read a paper before the Berlin Medical Society on the question of the transmission of tuberculosis by food and especially by milk. The announcement of a paper on this subject, which has received so much attention since the famous speech delivered by Professor Koch before the British Congress on Tuberculosis in London, attracted a large audience Professor von Hansemann stated that according to Professor Koch's opinion expressed at London *perlsucht* (bovine tuberculosis) was not communicable to the human subject, neither was human tuberculosis communicable to cattle. In his address read before the recent conference on tuberculosis at Berlin Professor Koch had dealt only with the question of the transmission of *perlsucht* to the human subject, not making any reference to the transmission of human tuberculosis to cattle Alluding to Professor Wolff, Professor von Hansemann said that some trustworthy observers had succeeded in making cattle tuberculous by the inoculation of the virus of human tuberculosis, the obvious inference being that the patient had either suffered from *perlsucht* or that both diseases were identical One of the principal arguments used by Professor Koch was that a collective investigation of cases, or alleged cases, of intestinal tuberculosis produced by food gave an absolutely negative result. It must, however, be remembered that Professor Koch only took cognisance of cases in which every other mode of infection could be excluded, a condition very difficult to satisfy Another of his arguments was that if the virus of tuberculosis were conveyable by milk or meat there would necessarily be epidemics of intestinal tuberculosis just as there were epidemics of enteric fever It was, however, unreasonable to compare an acute infection like enteric fever with a chronic disease which depended on so many casual circumstances The frequency of primary intestinal tuberculosis varied considerably in the estimates published by different authors. According to Dr Heller cases of primary intestinal tuberculosis were in the proportion of 3 78 per cent of all cases, while according to Professor Baginsky they were in the proportion of 4 1 per cent. The late Professor Virchow had stated that he had observed only three or four cases annually Professor von Hansemann's figures were practically identical with this for he had seen 25 cases in seven years. He said that the cases must be classified in four different groups (1) those in which only intestinal tuberculosis was present, neither the glands nor any other organ being affected , (2) those in which not only the intestine but also the mesenteric glands and the peritoneum were affected with tuberculosis , (3) those in which organs were affected which were never the seat of primary tuberculosis—such, for instance, as the pericardium and the meninges of the central nervous system , and (4) those in which tuberculosis was present in the lungs and the glands also but the lesions of these organs were obviously of a more recent date than those of the intestines where the ulcers had even partially healed In no instance had tuberculosis of the lungs appeared as a sequel of intestinal tuberculosis Tuberculosis of the peritoneum was sometimes observed in cases where the intestinal canal was healthy and it was therefore probable that tubercle bacilli were capable of passing through the intact mucosa of the intestine Professor von Hansemann then called attention to the fact that intestinal tuberculosis might be produced in other ways than through the medium of the food, as for instance, by the swallowing of the sputum by tuberculous patients. This was especially apt to happen with children, but, nevertheless, 40 children suffering from pulmonary consumption who were examined tuberculous ulcers of the intestines were found in only 10 It had been said by Professor Koch that butchers who dress the carcasses of tuberculous cattle are not liable to contract cutaneous tuberculosis on their hands or fingers, and this fact has been used as an argument against the possibility of *perlsucht* being communicated to the human subject, but it must at the same time be remembered that pathologists and those who work in dissecting rooms in various capacities very seldom suffer from tuberculosis of the skin, although examples of human tuberculosis are frequently passing through their hands. An investigation made by Professor von Hansemann showed that among 250 such persons who were examined, there were only four sufferers from tuberculosis of the skin and in no instance did general tuberculosis ensue The skin was, therefore, not very liable to become infected with tuberculosis Professor von Hansemann concluded his remarks by saying that tuberculosis might possibly be conveyed by food, but that such an event was extremely rare and that pulmonary tuberculosis was never a sequel of primary intestinal tuberculosis

Incomes of the Medical Profession.

The treasurer of the Berlin medical chamber has recently published a statement relative to the incomes of the profession in the district over which the chamber has authority As already mentioned in THE LANCET of Jan. 5th, 1901, p 70, medical men are required by law to pay a certain sum to the medical chamber of their district for the support of distressed medical men and their families The Berlin chamber decided two years ago that every medical man should pay a uniform sum of 10 marks (*10s*) and that those earning more than 5000 marks per annum should pay an additional amount equivalent to 5 per cent. of their income tax. In order that a fair assessment may be arrived at the Government tax office supplies the treasurer of the medical chamber with information relative to the incomes of the medical men concerned The statement now published shows that while the number of medical men in Berlin and the province of Brandenburg has risen from 3458 in 1901 to 3609 in 1902 an increase of 4 3 per cent. their income tax has increased in the same period from 774,470 marks to 832,393 marks, an increase of 7 4 per cent The aggregate income of the profession in this district has therefore risen, although not to any considerable extent. A small proportion —namely, 4 per cent.—of the profession had no taxable income at all , 26 9 per cent. had incomes between 900 and 3000 marks , 17 3 per cent had incomes between 3000 and 5000 marks , 27 8 per cent had incomes between 5000 and 10,500 marks , 17 8 per cent. had incomes between 10 500 and 50 000 marks , and 1 4 per cent had incomes from 50,000 to 220,000 marks In the remaining cases which made up the balance of 4 8 per cent. some points were still held under consideration by the tax office authorities. The statement then compares the incomes of the medical profession with those of the barristers who are in like manner taxed by their chamber The numerical results of the comparison are as follows 10 per cent. of the barristers and 30 8 per cent. of the medical men have incomes under 3000 marks , 12 per cent. of the barristers and 17 3 per cent. of the medical men have incomes from 3000 to 5000 marks , 50 per cent. of the barristers and 27 8 per cent. of the medical men have incomes from 5000 to 10,000 marks , 12 per cent. of the barristers and 7 5 per cent. of the medical men have incomes from 10,000 to 15 000 marks , 8 per cent. of the barristers and 4 7 per cent of the medical men have incomes from 15 000 to 20 000 marks , while 8 per cent. of the barristers and 7 per cent. of the medical men have incomes exceeding 20,000 marks. The average income is therefore higher in the legal than in the medical profession, and it must, moreover, be remembered that the medical chamber taxes a medical man's total income, both his professional earnings and his receipts from other sources, such as property yielding an annual return whereas members of the legal profession pay dues to their chamber on their professional earnings exclusively Dr Langerhans, a Berlin medical man and a member of the Prussian Diet, has united with other members in proposing that the Diet should alter the law so that (1) the medical chamber shall tax only the professional earnings of medical men and not their total income, and (2) that the tax shall be uniform This proposal, however, does not meet with general approval. It is said, for instance, that the Berlin medical chamber is now able to spend 50,000 marks annually out of its fund for the support of distressed members and it is obvious that if professional incomes only were taxed the only alternatives would be either a great reduction in the fund or a great increase in the rate of assessment. Moreover, it would be inequitable to tax the income of a hard working practitioner whilst another medical man who was in comfortable circumstances and did not practise was not required to pay anything

EGYPT

(FROM OUR OWN CORRESPONDENT)

Report on Malaria at Ismailia

LAST September Major Ronald Ross, I M S (retired), was invited by the President of the Suez Canal Committee to visit Ismailia and to advise on what steps should be taken to rid the town of malaria and readers of THE LANCET already know that in this mission he was voluntarily accompanied by Sir William MacGregor On arrival they found that Dr Dampeirou and Dr Pressat, the medical officers of the company, had already discovered many anopheletes in houses infected by malaria The population of the town amounts to only 7000 people, of whom at least 1000 are employed by the canal company The anopheletes found at Ismailia belonged chiefly to the two varieties, anopheles Pharoensis and anopheles Chandoyei. With the exception of one fountain in the middle of the European part of the town the ordinary irrigation supply of Ismailia was found to be free from anopheles, also the cesspools contained no anopheletes, though they swarmed with innumerable larvæ of the culex variety Several large marshes to the east of the town were filled up years ago in an effort to fight malaria, patients who had suffered from fever were regularly treated with quinine and all the employés of the company were well provided with mosquito nets, but Major Ross points out that the chief reason why these measures alone have not been successful is that the small ponds and pools have been neglected in times past. In these he found large quantities of anopheletes and he advised the authorities to fill up all those pools that exist and to put fish in the larger ones which cannot yet be filled in He thinks that this is a better method than dosing everyone indiscriminately with quinine, or than leaving the natives callously to their fate, and specially than by attempting to protect Europeans by mosquito-proof houses He advises that as far as possible the public should be educated on the mosquito question by public meetings pamphlets &c., and that not only the anopheles but also the culex should be summarily destroyed and he reminded the company that the culex pipiens and the stegomyia fasciata, both found in large numbers in cesspools, are capable of propagating elephantiasis and yellow fever He advises that special men should be told off to pour petroleum oil into every cesspool once a week, and judging from past experience, he promises that Ismailia, with an insignificant rainfall, can be rid of mosquitoes more easily than many other towns He ends his report by recommending at the desire of several of the inhabitants, that the town should be supplied with filtered water It is satisfactory to know that the work of destroying the mosquito is now being energetically pursued at Port Said, Ismailia, and Suez but so far the Government cannot be persuaded to do anything in this direction in Cairo

The Medical Congress at Cairo Malaria in Egypt

I think it will be well, although the medical congress is now a thing of the past, to say a few words about the discussions which took place upon malaria. Major Ross sent a paper on Malaria to the medical section, as he was unfortunately unable to attend in person. He pointed out the very great advance in the hygiene of warm countries which has taken place since the last medical congress held in the tropics, which was that of Calcutta in 1895. He believes the most important question now is to decide whether the gnats which do not belong to the genus anopheles are or are not concerned in the propagation of malaria and why certain individuals of one species of gnat are more dangerous than others. For instance, the researches of Stephens and Christophers demonstrate that the anopheles Rossii may be almost exculpated as an agent of malaria. His own personal experience of three years' constant attention to the subject in countries so different as water logged Assam and Lagos on the one hand and and Ismailia on the other has led him to believe that the best personal prophylaxis is the ordinary mosquito net during sleep and to this he adds the prophylactic administration of quinine when the danger is specially great. As mosquitoes seldom bite in the open air it seems an unnecessary policy to attempt to avoid them there, but he praises very highly the use of the punkah or the electric fan, together with the wholesale removal of breeding places of all kinds of mosquitoes. He ended his paper by desiring the medical profession constantly to urge, and if necessary to force, the public towards more general efforts against malaria. Dr Montaldo (Spanish Royal navy) also sent a paper based on his experience of malaria in the island of Fernando Po He is not at all converted to the mosquito theory but advises the use of the mosquito net to avoid the discomfort of insect bites He believes chiefly in general hygiene and in the prophylactic use of valerianate or hydrochlorate of quinine, which he recommends in doses of from four to eight grains taken fasting or before bedtime As a prophylactic he finds that a wafer of four grains taken every second morning is sufficient. Professor Mariani (Genoa) devoted a long speech to the praise of the Italians who have done so much in the elucidation of the malaria problem and he complained that Professor Koch and others had not given them sufficient acknowledgment. He cited a case where during Professor Koch's visit to Rome two years ago Professor Baccelli saved the life of a man moribund from pernicious fever by an intravenous injection of quinine. Professor G Gaglio recommended very highly the hypodermic injection of quinine which he gives with urethane in the proportion of 2 of hydrochlorate of quinine to 1 of the latter Yellow fever is not a disease which attacks Egypt and the only mention of it in history is by Baron Larrey during the French occupation 100 years ago, whose cases were almost certainly either relapsing fever or Griesinger's bilious typhoid fever Major Gorgas (United States Army Medical Corps) contributed an interesting paper on the Sanitation of Yellow Fever in Cuba He pointed out that in times past there have been several instances of large bodies of men being almost entirely destroyed by this disease, the French expedition in 1802 to Haiti lost 22,000 out of 25,000 men from yellow fever in one season. Again, quarantine in the last generation has caused great financial loss, for instance, it is estimated that the loss to the Mississippi valley by the last great epidemic of 1878 was not less than £20 000 000 In 1898 when the Americans took possession of Havana they found that the death rate was 91 per 1000 but in consequence of improved sanitary conditions the mortality fell in 1899 to 33, in 1900 to 24 and in 1901 to 22 11 but to their great disappointment all their sanitary efforts had no effect on yellow fever which, on the contrary grew worse and worse, the year 1900 being one of the severest epidemic seasons even for Havana, which had been recorded for the past 140 years. A special board was appointed to study the disease, and this board discovered the truth of Dr Finlay's (Havana) contention that a certain species of mosquito was the means of transmitting the disease from person to person After many experiments it was found that a stegomyia which was allowed to bite a yellow fever patient within the first three days of the disease, kept for from 12 to 20 days, and then allowed to bite a non immune individual, almost invariably transmitted the fever The period of incubation was proved to be from three to six days, the shortest time being two days and 22 hours and the longest six days and two hours When once it was proved that the stegomyia was the real cause of the disease the following arrangements were carried out —1. The quarters of the patient were screened with wire netting within two hours after the case was reported and a guard was placed over the quarters to see that the one wire door was kept closed, immune persons only being allowed freely to pass 2 Arrangements were made to kill all mosquitoes which might have become infected before the screening of the patient, both in his own house and in all the neighbouring houses For this pyrethrum was burned in the room at the rate of 1 pound to 1000 cubic feet of space, after which the mosquitoes were carefully swept up and destroyed. 3 Five days' quarantine was maintained to keep out of the town people who might be suffering from yellow fever or incubating for it. 4 Brigades were organised for the destruction of mosquito larvæ in all parts of the city and suburbs. In January, 1901, just before the mosquito brigades were organised, an inspection of the whole city showed that mosquito larvæ existed in 26,000 different places in the city A year later a similar inspection showed less than 300 deposits of larvæ in the same area The destruction of the mosquito also reduced the malaria mortality in 1900 from 344 to 151 in 1901 The fight against yellow fever was begun in February, 1901, and on Sept. 28th of the same year the last case of yellow fever occurred in Havana. Since that time, now more than a year ago, not a single case had originated in the city, this being the first time that the disease had been absent from Havana for all the years that statistics have been taken. The Medical Congress passed a vote of condolence with the family of the late Major Walter Reed who, as readers of THE LANCET are aware, died quite lately in Washington after an operation for appendicitis He was one of the foremost bacteriologists and pathologists of the United States and he acted as president of the board of army medical officers in Havana who taught the world how to eradicate yellow fever Dr Terni (Messina) also contributed a paper on Yellow Fever which he had studied in Brazil and expressed the belief that the "*bacille icteroide*" is the specific cause of that disease

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Hospital for the Treatment of Tuberculosis in New York City

IT is computed that there are in New York 19,000 persons suffering from tuberculosis The facilities for taking care of consumptives are very inadequate, in fact, it has been shown that New York is far behind London and most of the other large cities in regard to provision for the care of sufferers from pulmonary tuberculosis The matter has been taken up recently by the lay and medical journals and by the medical profession. The *New York Herald* has advocated editorially the establishment of hospitals and sanatoriums for indigent consumptives. On the evening of Jan. 3rd Dr Henry P Loomis spoke in favour of this course He drew attention to the fact that New York city was actually worse off now than it was ten years ago in the matter of taking care of consumptives for since tuberculosis has been regarded as a communicable disease its victims have been barred from the general wards of the city hospitals. The majority of the cases are in the tenement districts where the danger of infecting healthy people is very great on account of the overcrowding and the ignorance of this class Dr Loomis therefore thinks that now is the time for the city government to take practical steps, as has already been done in most of the large cities abroad, to establish a large and thoroughly equipped consumption hospital, he is further of opinion that such a building should be erected on Blackwell's Island where there is plenty of room and where the patients can have the maximum amount of sunlight and air In connexion with this main consumption hospital an annexe should be built in the country near New York. This annexe should be constructed on the pavilion plan and should be intended for those hopeful cases where the sufferers are in the early stages of the disease. Great interest is being taken in the question of tuberculosis by rich men in this country Mr Phipps the other day gave more than £200 000 to Philadelphia for the purpose of studying and treating the malady, while Mr Rockefeller has given to the University of Chicago a much larger sum to be devoted to research work especially in tuberculosis It thus seems probable that New York will soon have the necessary institutions for its consumptive poor

Adulteration of Drugs in New York City

The practice of substituting inferior or impure drugs for those ordered has been exercising the minds of New York physicians for some time So common has this practice on the part of druggists become that recently many physicians, as well as local medical societies and associations, submitted a large number of samples of different drugs and chemical agents to the department of public health with the request that they should be analysed Phenacetine is the particular drug which at present is looked upon with suspicion, and out of a total of 373 specimens purchased from druggists in Greater New York no less than 365 have been found to be adulterated. Many other drugs have been discovered to be not up to the standard of the requirements of the United States Pharmacopœia and the health board intends to pursue its investigations on a large scale

Charges against Bellevue Hospital

Once again grave charges, reflecting seriously upon the management of Bellevue Hospital, the large city hospital of New York, have been made Some two or three years ago the scandals originated by accounts of cruelty which occurred in Bellevue Hospital became so notorious that public opinion was much agitated and finally a board of trustees investigated the matter and made a report. The report stated that many evils existed in the system of management, and that the nursing especially was faulty The board of trustees presented a scheme for reorganisation and among other suggestions the recommendation was made that all the old buildings known as the Bellevue Hospital should be pulled down and that a thoroughly equipped modern hospital should be erected on their site Similar recommendations were made with regard to the other city hospitals Despite these recommendations it would appear that few measures of reform have been introduced, for the charges which have been recently brought against the management are in the main identical with those preferred many times previously A searching investigation is now being undertaken by the district attorney's office The *Medical Record* and other New York medical journals insist strongly that the present system of management should be altered and that hospitals in keeping with the size and wealth of New York should be provided by the city

(FROM OUR OWN CORRESPONDENT)

Tuberculosis in Victoria

A DEPUTATION from the Victoria Association for the Prevention and Cure of Tuberculosis recently waited on the Minister of Health and appealed for a Government grant for the care of practically incurable cases of tuberculosis. The Austin Hospital was prepared to make provision for the cure and treatment of 60 additional consumptives if the Government would bear half the cost. Dr J Jamieson, health officer of the city of Melbourne, stated that between 1800 and 1900 persons died in Victoria every year from tuberculous disease and that there were at least from 5000 to 6000 sufferers from tuberculosis in the State. Of these probably 1500 might be regarded as being in a tolerably curable stage The only accommodation provided was at the Macedon and Echuca sanatoriums for 50 cases. The only provision for the remaining incurable cases was at the Austin Hospital, to the extent of 80 cases a year, and the Melbourne Hospital where 150 cases a year were treated The Minister of Health admitted that a very good case had been made out by the deputation and said that he would place its views sympathetically before the Cabinet but in the present state of the finances he could not promise that the Government would do anything He suggested that the money should be raised by public subscription

The Financial Position of the Medical Charities in Victoria

The Government of Victoria in pursuit of its retrenchment policy has reduced the charities grant by £20,000 Owing to the drought the prices of provisions, and, in fact, of everything, are exceptionally high Consequently the managers of the various hospitals are in a very serious financial difficulty Their expenditure is increased and their income is diminished. A deputation of representatives of the various hospitals recently met the Treasurer to the Government to discuss the position. The deputation asked that effect might be given to the recommendations of the Charities Commission If some assistance was not forthcoming the various institutions must close some of the wards The Minister, in reply said that the old age pensions must have relieved the demands on organised charities or private individuals by more than £20 000 He thought also that the charities were abused, by want of closer discipline the benefits of charity had been given to many who personally or through relatives might have paid. The inspector of charities in his last report said "The number of really destitute cases was comparatively small, the hospitals are used by persons not able to pay the ordinary medical fee yet able to make a small contribution to the institution." Taking the Melbourne Hospital as an illustration only £60 were contributed in sums under £1. The people who could give small amounts were those who received the benefits of the charity The charitable institutions altogether obtained from private subscriptions, entertainments, and collections £65,000, from municipal grants £11,000, as interest on investments £11 000, from patients' contributions, £16,000, from out-patients' fees, £5000, from legacies, £15 000, and from the Government, £110,000 He regretted that he could not see his way to give more aid from the Government. Speaking as an individual and not as the Treasurer of the State, he would like the charities to have an endowment by a tax on sports and the totalisator It has been pointed out, however that the managers of the charitable institutions can do nothing more, the suggestions of the Treasurer could only be carried out by Parliament. Economy has been carried to its extreme limits The debit balance at the Melbourne Hospital for the year is now £6793. The Queen Victoria Jubilee Fever Hospital is no nearer a solution of its difficulties. A conference of municipalities in the metropolitan area has been held. A basis for discussion was presented, providing (1) that half of the cost of maintenance should be provided by the metropolitan municipal councils and half by the Government, and (2) that all the metropolitan municipalities should contribute in proportion to municipal property assessment. Unfortunately the Premier stated that the Government would not provide half the money required and so far only eight out of 24 municipalities concerned have approved of the scheme, while seven actively disapprove.

New Out-patient Department at the Sydney Hospital for Sick Children.

A new out-patient department has just been opened in connexion with the Sydney Hospital for Sick Children It is situated at the corner of Quay street and Valentine lane It is close to the new central railway station and the George street trams. The site has been obtained on a 50 years' lease and the estimated cost of the buildings is £3000 There are a large waiting hall to seat 200 persons, with provision for future extension, an examination room at the entrance with a special room for suspect cases, and four consulting rooms, an adequately fitted operating theatre, a large dispensary and attached waiting hall, and house surgeons and nurses quarters Special arrangements are made for a constant circuit of patients.

Prince Alfred Hospital Sydney

The enlargement of the Prince Alfred Hospital, Sydney, from 161 to 236 beds has necessitated changes in the staff. To relieve the medical superintendent of much of the work of directing the non medical staff it has been decided to extend the functions of the secretary by making him the chief non medical officer under the medical superintendent Revision of the rules was also necessitated by the creation of the new positions of resident pathologist, registrar, and anæsthetist, clinical assistants to the out-patient department, and honorary pathologist. The matron will in future be known as the matron and superintendent of nursing, the trained staff will consist of sisters, charge nurses and staff nurses and the pupil nurses will be graded as first, second and third year pupil nurses. Two new senior positions have been created in the matron s assistant and the housekeeper, both of which will be generally filled by sisters the sister acting as housekeeper being changed every six months so that all may receive adequate instruction in this branch of hospital management. The directors have also had under consideration the question of lightening the nurses' duties particularly during their first year of service. It is held that a certain amount of manual labour, such as scrubbing woodwork, &c, is essential as a test of the physical capacity of candidates for the nursing profession to stand the strain which they must undoubtedly undergo But it has been decided that, except during a short probationary trial, they may be relieved of much of this work and to permit of this being done wardmaids are for the future to be employed. These will do the rough works of wards, thus leaving the nurses free to carry out their more distinctive duties As the work of the nurses will thus be lightened to a great extent it is anticipated that the demand for positions upon the nursing staff will be even greater than at present. To meet this condition of things it is proposed to raise the status of the nurses by making the position more of an honorary one than at present and by giving an honorarium instead of a salary, which will rise by annual increments over a term of three years.

University Dental Hospital, Sydney

The Senate of the University of Sydney has received a report from Mr R. Fairfax Reading, chairman of the University Dental School committee, upon the work of the University Dental Hospital for the year 1902. The hospital was opened to the public on Jan. 7th and even without making allowances for delays and interruptions, due to vacations and the University jubilee celebrations, the record of the work was the report states, highly satisfactory The total number of patients who had attended at the hospital for treatment in all departments was 3964—a convincing proof of the wisdom of the action of the Senate in establishing the hospital The committee had taken every precaution to prevent the hospital being abused by those who could well afford to go to a dentist and thereby to assure to the deserving poor the full enjoyment of its benefits The committee considered that the amount of clinical work done by the second year students, who only number nine, reflected great credit upon the students. In March next 11 students at present in their first year would be ready to undertake clinical work and it would then be necessary to provide at least six more dental chairs in addition to the 11 with which the hospital is now supplied. "The increasing amount and variety of conservative dental work which the students are called upon to undertake," the report concludes, "renders the hospital an important addition to the dental school and will in future be a guarantee that the dental graduates of the University of Sydney will be thoroughly competent to successfully undertake any operation incidental to modern conservative dental surgery"

Preservatives in Food

The Board of Health of New South Wales has published amended regulations under the provisions of the Public Health Act, one of the most important of which is as follows —

> (a) Any one antiseptic or any one antiseptic preparation may be mixed with any food in proportions not exceeding one one-thousandth of one grain per pint in the case of liquid foods and of one one-thousandth of one grain per pound in the case of solid foods provided that the label required by section 56 subsection 2, of the Act to be affixed to the vessel or parcel containing food mixed with antiseptics or with antiseptic preparations in accordance with this regulation be in the form given in Schedule L and be printed on a white ground in black capital letters of the size known as two-line brevier sans serif and contains no other matter (b) The following substances shall be deemed to be antiseptics and antiseptic preparations for the purposes of this regulation Formaldehyde and its preparations boric acid and its preparations hydrofluoric acid and its preparations sulphurous acid and its preparations benzoic acid and its preparations salicylic acid and its preparations and derivatives of coal tar whether direct or indirect

The regulation will come into force on Feb 2nd.

Obituary.

EDWARD EUSTACE, M D DURH, L.R.C P EDIN L.R.C S. IREL.,

SURGEON LIEUTENANT-COLONEL A.M D

DR. EDWARD EUSTACE died at his residence, Underwood, Cheltenham, on Feb 16th, in his sixty second year The deceased obtained the qualifications of L.R.C S Irel and L R.C.P Edin in 1863 and 1864 respectively and graduated M.D of Durham University in 1886. Shortly after qualifying he entered the Army Medical Department and whilst in the service was in charge of the Women and Children s Hospital at Netley in 1873–74 the European and Native Female Hospitals at Agra in 1881, and the Women's

Hospital, Landour, in 1882, and he was also medical superintendent of the Military Hospital, Devonport, in 1884 Shortly after receiving his promotion to surgeon major he retired from the service with the honorary rank of surgeon-lieutenant-colonel He then commenced practice at Weston super Mare and married the daughter of General Rawlins of that town. After remaining for several years in Weston super Mare Dr Eustace removed to Cheltenham and practised there. The deceased was extremely popular in Weston super-Mare and in Cheltenham and much sympathy is felt for his widow and her young children.

Final Examination in Midwifery —Robert J Fleming William G Harvey William R P M Neight Charles E Moore, Joseph Wallace and Douglas B Thomson

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, MARYLEBONE ROAD, N W —The annual meeting of subscribers of Queen Charlotte's Hospital was held at the hospital on the afternoon of Feb 23rd, the Earl of Hardwicke presiding The report stated that 1271 women had been treated in the hospital during the past year and 1204 had been attended at their own homes. The expenditure had amounted to £5183 King Edward's Hospital Fund had made a grant of £1000 to the hospital and £50 to the convalescent home In moving the adoption of the report Lord Hardwicke referred to the continued increase in the work of the charity and its importance as a training school in midwifery and monthly nursing The new regulations extending the period of training for midwives and nurses had been in force for a year and had proved very successful He also referred to the passing of the Midwives Act and to the leading part that the hospital had always taken in the training of midwives To maintain the hospital in efficiency upwards of £5000 was needed yearly, but the assured income amounted to only about £2000 He made an earnest appeal for further funds—especially new annual subscriptions—to provide the deficiency

FREEMASONRY —*The Middlesex Hospital Lodge, No 2843* —A meeting of this Lodge was held at the Freemasons' Hall on Thursday, Feb 19th, Bro William Duncan, W M , in the chair Bro Percy Noble was admitted to the third degree. Messrs J Elsdale Molson, Sidney Herbert Lee, and Walter James Susmann were initiated into Freemasonry Bro F J Wethered was elected W M. for the ensuing year and Bro Henry Morris was re-elected treasurer The brethren and visitors subsequently dined together

OBSTETRICAL SOCIETY OF LONDON —The following is a list of officers of this society for 1903 —President Dr Edward Malins. Vice Presidents Dr William Japp Sinclair, Dr A. H Freeland Barbour, Dr John Phillips, and Dr Herbert R Spencer Treasurer Dr George Ernest Herman Chairman of the Board for the Examination of Midwives Dr W R Dakin Honorary secretaries Dr Amand Routh and Dr Montagu Handfield-Jones Honorary librarian Dr Robert Boxall.

THE JOHNSTON LABORATORY, UNIVERSITY COLLEGE, LIVERPOOL —Mr Long, President of the Local Government Board, will open the Johnston Laboratory at University College, Liverpool, on May 9th This laboratory, which has been built and equipped by Mr William Johnston of Bromborough, will include accommodation for the following departments of the college bio-chemistry, under the direction of Professor Benjamin Moore, D Sc., tropical medicine, under Major Ronald Ross, C B., F R.S., experimental medicine and comparative pathology, together with cancer research, under Dr A S F Grünbaum Mr Johnston has endowed the professorship of bio-chemistry and three fellowships in various branches of medical research, while, as we have already mentioned, the scheme for the investigation of cancer has been recently provided for by Mr T Sutton Timmis with a gift of £10,000

UNIVERSITY COLLEGE HOSPITAL —In January, 1882, Mr Newton H Nixon, the secretary, published a history of University College Hospital from its foundation to the year 1881 and he has now supplemented that volume by a pamphlet containing a "Record of Events from 1882 to 1901 inclusive." This is not a continuous narrative but consists of detached paragraphs alphabetically arranged. For instance, under letter B the entries are "Balls, Bazaars, Beck Memorial, Beds named Beds closed, Beds, re-opening of," and so on through the alphabet, concluding with "Students' distinctions, University College Hospital Ladies' Association, Wakley Convalescent Home, Wards named." The most important event in the recent history of the institution is chronicled under the heading "Rebuilding of Hospital" the prime mover in which work is Sir J Blundell Maple, Bart., M P The new buildings were commenced in September, 1897, the foundation stone was laid by the then Prince and Princess of Wales in June, 1898 and various departments were opened at different times in 1900 and 1901 As the "Record" is only brought up to the end of 1901 the great progress made during 1902 is not referred to. The account of the Wakley Convalescent Home mentions the bequest of a freehold residence and land at Longcross, near Chertsey, by Dr James G Wakley, Editor of THE LANCET, in 1886 and the subsequent negotiations by which, with the consent of the Charity Commissioners, the property was sold and the Wakley Convalescent Fund was created.

DONATIONS AND BEQUESTS —Under the will of the late Sir Joseph Sebag Montefiore the London Hospital, the Ramsgate Seamen's Infirmary and General Hospital, the Beth Holim Hospital, Mile End road, and the Jews' Hospital and Orphan Asylum, Lower Norwood, receive £100 each.—One-eighth of the estate of the late Mrs. A. M Travers which has been valued at £1916, has been left in trust for the Royal Hospital for Incurables at Donnybrook, Dublin.—A legacy of £500 has been bequeathed to Addenbrooke's Hospital under the will of the late Mr Mr E J Mortlock.—Under the will of the late Mr Albert Bousfield provision is made for legacies of £200 each to the London Hospital, the Middlesex Hospital, St Mary's Hospital, the Great Northern Central Hospital, the Fulham Cancer Hospital, the City of London Lying in Hospital, the Royal Eye Hospital, the Alexandra Hospital for Hip Disease, the Samaritan Free Hospital in Marylebone road, and the Sussex County Hospital.—Miss Barbara Matthew Ross has by her will bequeathed to the National Industrial Home for Crippled Boys at Kensington, £400, to the Society for the Prevention of Cruelty to

Animals, £400 , to the Royal Sea Bathing Infirmary at Margate, £200 , to the Metropolitan Convalescent Institution, £200 , to St. Mary's Hospital, £200 , to the Samaritan Free Hospital for Women and Children in Marylebone-road £200 , and to the New Hospital for Women in Euston road, £200 — Under the will of Mr Jacob Uttley £100 are bequeathed to the Rotherham Hospital and the Royal Hospital and the Royal Infirmary and the School for the Blind Sheffield, receive £100 each

WALTON CONVALESCENT HOME—The annual report of the Walton convalescent home near Clevedon states that 538 patients were admitted during 1902, being 60 more than the maximum of previous years The financial statement showed that the income amounted to £983 and that a favourable balance of £8 remained.

SUCCESSFUL VACCINATION GRANT—A notable record has been established by Mr J B G Gidley Moore, M.R C P Edin , L.R C P Lond., of Ongar Essex, who has been public vaccinator for the No 1 District of the Ongar Union for 28 years and who during that period has always obtained the award under the provisions of Section 5 of the Vaccination Act 1867

HEALTH OF DEVIZES —The annual report of the medical officer of health of Devizes states that the population numbered 6532 and that the birth rate for the year 1902 was 22 6 per 1000 The death rate for the same period was 11 7 per 1000 More than half of the deaths were of persons over 66 years of age and one of those deceased was over 100 years of age

FALMOUTH SEWAGE—At the meeting of the Falmouth town council held on Feb 12th the mayor (Dr W Bunks) moved

> That immediate steps be taken to carry out the undertaking of a sewage scheme as set forth in a resolution passed in April 1902, or failing this, to repay the loan of £1000 sanctioned on the understanding that the council would submit to the Local Government Board revised plans and estimates of a drainage scheme for the borough.

Eventually the motion was carried by 9 votes to 3.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Earlier Closing of Shops

IN the House of Lords a Bill has been introduced by Lord RIBBLESDALE to enable local authorities to fix an hour for the closing of shops

Sir Michael Foster's Position

Intimation has been conveyed to the party whips that for the future Sir Michael Foster Member for the University of London will sit on the Opposition side of the House.

The Disciplinary Powers of the General Medical Council.

The Bill framed by the General Medical Council for strengthening its hands in dealing with penal cases is once more before the House of Commons. It was introduced on Feb 23rd by Sir John Batty Tuke who has a double interest in the measure in respect of being a member of the Council and the Parliamentary representative of the Universities of Edinburgh and St Andrews. The Bill has three main provisions In the first place it gives the Council power to remove from the Medical Register for a limited period of time practitioners who have been convicted of crime or who have been adjudged by the Council to have been guilty of infamous conduct in a professional respect. In the present state of the law the Council can simply remove from the Register and restoration is obtained by process of application. The second main provision of the Bill enables all medical licensing bodies summarily to deprive of his diploma or diplomas the practitioner who has been removed from the Register by the Council in respect of misconduct. Some of the bodies but not all possess this power already The third main provision enacts that fines and penalties recovered under the Medical Acts shall be paid to the Council and applied in aid of the expenses of the Council in administering these Acts The Bill is backed by Sir John Batty Tuke Sir Richard Jebb r J A. Campbell Sir Michael Foster Mr Talbot and Sir John Gorst. It has been read a first time and its second reading has been put down for April 24th when there is little or no chance of its being reached in time for discussion. It is matter for regret that a measure of this kind affecting as it does the efficient administration of important Acts of Parliament should not have been taken charge of by the Government instead of being left in the hands of a private Member

HOUSE OF COMMONS

WEDNESDAY FEB 18TH.

Housing of the Working Classes

During the debate on the Address this subject was discussed at considerable length on an amendment proposed by Dr MACNAMARA in which it was declared that the greatest hardships are inflicted upon many of the working-class population by reason of the lack of proper housing accommodation and that immediate parliamentary attention to this evil is one of the most pressing of the necessities of domestic policy Complaint was made against the Local Government Board for remissness in connexion with the administration both of the Public Health Acts and the Housing Acts —Mr WALTER LONG in reply defended his department and said that too often when he attempted to bring pressure to bear on local authorities to induce them to discharge their duties more effectively and to appoint properly qualified officers it was the local Member of Parliament who came to him and protested that he was unduly severe He frankly admitted that there was great need for effective administration in regard to sanitary matters and he appealed to Members of Parliament to support the Local Government Board in its efforts in this direction Mr Long intimated that he proposed during the present session to introduce a Bill dealing with certain minor matters connected with the housing of the working classes including the extension of the period for the repayment of loans

THURSDAY FEB 19TH

Boards of Guardians and their Officers

Mr MORRELL asked the President of the Local Government Board whether his attention had been called to the position in which boards of guardians were placed through want of control over the officers whose salaries and pensions the ratepayers were called upon to provide and whether he would cause inquiry to be made into the matter with a view to the provision of a remedy —Mr LONG replied I have received a resolution on this subject from the Woodstock board of guardians Boards of guardians possess considerable powers of control over their officers and except in the case of their principal officers have the power of dismissal. As regards the principal officers the consent of the Local Government Board is required to dismissal, but where there is cause for dissatisfaction it is competent to the guardians to make representations to the board.

FRIDAY FEB 20TH.

Private Members Bills Introduced

A number of Bills were introduced by private Members and formally read a first time, amongst them being a Bill to amend the law relating to the qualification and tenure of medical officers of health and inspectors and to make further provision relating to superannuation allowances for such officers and inspectors a Bill to provide for the registration of plumbers and a Bill to provide that no prosecution under the Vaccination Acts shall be commenced without the authority of the guardians No one of these three Bills has obtained a favourable place in the order paper for second reading

MONDAY FEB 23RD

General Laurie and the Medical Acts

At this sitting General LAURIE introduced his two Bills to amend the Medical Acts so as to facilitate the registration in this country of colonial practitioners Unfortunately for the progress of the measures neither of them has obtained a favourable place in the orders for second reading

Lead Poisoning in the Pottery Trade.

Sir CHARLES DILKE asked the Home Secretary whether he could give the House any information as to the working of the compensation scheme instituted by the master potters for injuries caused by lead and alluded to in the arbitration on the Home Office rules and whether His Majesty's Government had been informed by the Potters' Association of the progress of the scheme and of the extent to which masters and men had coöperated to make its advantages general.—Mr AKERS-DOUGLAS replied I am informed that 72 firms have joined the Potters Assurance Association and that three others are insured on the same lines in other ways Most of these firms are of importance in the trade and as far as my information goes the scheme appears to be working satisfactorily with the exception that in eight factories as I understand the men have refused to submit to the medical examination which is an essential part of the scheme

The Board of Education and Physical Training

Dr MACNAMARA asked the Secretary to the Board of Education whether he would consider the desirableness of replacing the recently issued model course of physical drill for children by a course more suited to the needs of young children than the present compilation which was prepared from the Soldiers Drill Book.—Sir WILLIAM ANSON replied The Board of Education has no present intention of replacing the model course of physical training But it is considering the desirableness of issuing a kind of introduction to the model course showing the steps by which the series of exercises in it may be progressively acquired. This will greatly assist the managers of the smaller schools in introducing it I may remind the honourable Member that though the Board strongly advocates a uniformity of system, both in the interests of the teachers (on whom falls the burden of imparting the physical training) and in those of efficient instruction it is prepared to consider (and has in many cases approved) alternative schemes having the same scope and aim as the model course

TUESDAY FEB 24TH.

Ventilation of Cotton Factories

Mr SHACKLETON asked the Home Secretary whether he could state what number of employers were reported during the year 1902 by the inspector under the Cotton Cloths Factories Act as having exceeded the nine volumes of carbonic acid (carbon dioxide) in every 10 000 volumes of air (Factory and Workshop Act 1901 Clause 94 section 3) and whether he could state the number of prosecutions which had been instituted by the Home Department in consequence of these reports.—Mr AKERS DOUGLAS replied : There were 63 cases in 1902 in which the inspector reported that an employer had exceeded the standard referred to but in many cases the excess was found only in one part of the shed while in other parts the proportion of carbonic acid was found to be below the prescribed limit. No proceedings were instituted on these reports I do not think the inspectors are called upon to prosecute unless a contravention of the Act in this matter is continued or repeated after notice from the inspector

Alcohol and Lunacy in Ireland

Mr James O Connor asked the Chief Secretary to the Lord Lieutenant of Ireland (1) if he had seen the report read by Dr Norman Conolly at the recent meeting of the Richmond Asylum in which reference was made to the increase in the number of cases of alcoholic lunacy committed to that institution (2) whether he was aware that the Richmond Asylum authorities had since the year 1900 made several representations to the Irish Government on this matter and (3) whether in view of the state of the law as regards the care of alcoholic lunatics and considering the revenue derived by the State from the sale of intoxicating liquor he would recommend the establishment of a State infirmary in Ireland for the treatment of persons who had become insane from excessive indulgence in intoxicating drinks — Mr Wyndham replied The reply to the first and second queries is in the affirmative. The concluding part of the question suggests an amendment and widening of the existing law which provides for the establishment of institutions for the reception of habitual drunkards under certain prescribed conditions I cannot give an undertaking such as is suggested

Sanitary Condition of the House.

Mr Wylie asked the Member for North Hunts, as representing the First Commissioner of the Board of Works when the report of the Select Committee appointed to inquire into the ventilation of the House of Commons building would be issued and what steps, if any had been taken during the recess to remove some of the insanitary conditions —Mr Ailwyn Fellowes said: The Select Committee found it impossible to conclude their inquiry last session and it is proposed to ask the House to re-appoint the committee at an early date During the recess the authorised improvements in the ventilation of the Commons committee-rooms have been completed and new fittings have been supplied to the sanitary offices on the ground floor terrace front and mechanical ventilation has been introduced into them with excellent results Other sanitary offices in the building will be dealt with in the same way as opportunities arise during recesses

WEDNESDAY, FEB 25TH.

Sewage Contamination of Shell fish.

Sir Joseph Dimsdale asked the President of the Local Government Board whether his attention had been called to a recent report of the medical officer of health for the City of London on shell fish and sewage; and whether he would take any and if so what action in the matter — Mr Walter Long replied: Yes sir my attention has been called to this report The Royal Commission on Sewage Disposal are taking evidence and making investigations on the subject of dangerous contamination of shell fish by sewage with a view to ascertaining the measures necessary for obviating risks to the public health from this cause I have caused to be sent to the commission a copy of the report referred to and other reports relating to this matter

MARRIAGES.

Dobson—Millington —Feb 24th at the parish church, Davenham, Cheshire by the Rev J J James M.A. Joseph Faulkner Dobson M.S. (Lond.) F R.C.S (Eng) eldest son of Joseph Dobson M.D (Lond) of Burley Leeds to Minnie, youngest daughter of the late Thomas Millington of Hope Flintshire.

Gordon Smith—Newbery —On Feb. 18th Harry Gordon Smith M.A. M.B Cantab. to Amy Eileen youngest daughter of Frederick Newbery of Milton Ernest, Bedford

Moore—Nolan —On Feb. 11th at Cairo Egypt Cecilia Eva Gladys de Radclyffe, eldest daughter of Beaufoi Moore, of the Middle Temple and Ashingdon, Essex barrister at law and of Mrs. Beaufoi Moore to Harold Nolan LL.B M.B Lond. F I C

DEATH.

Peregrine.—On Feb. 18th, at the Firs, Woking Thomas Peregrine M.D Edin in his 93rd year

N.B —A fee of 5s is charged for the insertion of Notices of Births, Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE NATIONAL ANTI VIVISECTION HOSPITAL.

In The Lancet *of June 14th 1902, p 1705 we referred to a circular* concerning Hospital Sunday sent out by an association called the Church Anti Vivisection League. The association in question recommended subscribers to allocate their subscriptions to a hospital which was just about to be opened The hospital is now in working order and is called the National Anti-Vivisection Hospital. We referred in our former article to the staff of the hospital. It consisted of 26 members some of whom lived in Cornwall, Gloucester Oxford, and other places *distant from London.* From a *circular which* we have now received it appears that the staff is reduced to 11 members ten of whom live in London and one in Greenhithe. Of the ten two are homœopaths. The senior member Dr Alexander Bowie, is credited in the Medical Directory with being the editor of 'Harvey on the Circulation of the Blood" which seems to us to be inconsistent with being a pronounced anti vivisectionist But it is not the circular dealing with the hospital to which exception can be taken so much as an *inordinately silly reprint from the Verulam Review entitled* A Visit to the National Anti Vivisection Hospital." In this effusion we find platitudes such as the following The Laboratory (hateful name from its association with vivisectional experiments) is here called the Dispensary and is daily supplying its medical aids" We never heard of a hospital dispensary being called anything but a dispensary but after all a laboratory only means a place to work in The paper before us reiterates the charge that when the doctors of an hospital have allowed themselves habitually to perform painful experiments on animals the sick poor under their charge must always be in danger of similar experimentation at their hands" The paper implies that because the new hospital has no vivisector on its staff, no vivisection in its schools (so far as we know it has no school) and allows no experiments on patients therefore its treatment is far better than that at any other hospital. In the brief particulars of individual cases" we find the following one gravely set out —

> A charwoman, dependent on her own earnings and afflicted with a partially paralysed leg—think of this readers who have two good legs and nothing to do with them but to amuse yourselves with walks and rides and games—has been much helped not only with strengthening medicine, but with a valuable surgical instrument .. .. She blesses the hospital."

We cannot refrain from quoting a case in which the reasoning is somewhat similar —

> Thomas Burton, has a wooden leg used to wear second hand wooden legs and drink a glass of hot gin and water every night Found the second hand wooden legs split and rot very quickly is firmly persuaded that their constitution was undermined by the gin and water Buys new wooden legs now and drinks nothing but water and weak tea. The new legs last twice as long as the others used to do —(Jonas Mudge, quoted in Posthumous Papers of the Pickwick Club.")

But to be serious Do the board of management the medical staff and the medical patrons of this hospital think that its cause will be advanced among *thinking persons* by the publication of such twaddle as we have quoted? Also are they prepared to use no treatment or means of cure which has been found out by means of experiments on animals? Dr Bowie who was interviewed by the writer of the paper before us makes a great point of the successful treatment of wasting babies We should like to ask him how he will treat a case of cretinism or of myxœdema? Will he prescribe thyroid gland? Will the surgeons of the hospital ever tie an artery in its continuity for aneurysm? If they do they will be profiting by experiments made upon animals If they do not they will not be doing their best for their patients We leave Dr Bowie and the surgeons to get out of this dilemma in the best way that they can

A COURSE OF READING

To the Editors of The Lancet

Sirs,—Would you kindly suggest in the next issue of The Lancet what you consider the most suitable text books to read for the B.S (University of London) examination (including the examination for honours)? Thanking you in anticipation,

I am, Sirs yours faithfully

Feb 13th, 1903.

Bachelor.

*** The most suitable books for the B.S (University of London) are The International Text-book of Surgery" by Gould and Warren, and Treves's Operations of Surgery" The ordinary works on anatomy should be studied and in addition Treves's Surgical Anatomy" It is always well for a candidate for honours at the B.S examination to read special works such as Sheild's Diseases of the Breast," Treves's Intestinal Obstruction," Butlin's Diseases of the Tongue," Bland Sutton's Tumours" and so on. This advice is given with the limitations which our correspondent will find in our leading article on p. 593 while the advice of his lecturers might also be sought with advantage.—Ed. L.

EMPLASTRUM BELLADONNÆ.

To the Editors of THE LANCET

SIRS —Our attention has been drawn to a letter from one of your correspondents relative to emplastrum belladonæ We have made this plaster at our Warwick works for over 30 years and may safely say that such a complaint as blistering by this plaster has never reached us During the whole of our experience we have only had two or three complaints at the outside of our belladona plaster ' irritating It is ten years ago since we even had those

The component parts of the plaster should be so blended that even irritation should be next to impossible but on very highly sensitive skins slight irritation may occur, causing redness but certainly not blistering I am Sirs yours faithfully

London Feb 17th 1903

UNFOUNDED ACCUSATION AGAINST A MEDICAL MAN

ON Feb 17th and 18th Mr Justice Jelf and a special jury heard the case of Pride *v* Mellish in which George Frederick Pride a farmer of Tetbury sued John Stafford Mellish M R C S Eng L.R C.P Lond for assault The assault was not denied but was justified on the ground that the plaintiff was behaving in an unseemly manner The plaintiff went to the defendant's house as he was courting the parlourmaid. The defendant finding him in the house put him out into the road and horsewhipped him. The parlourmaid who was called for the plaintiff made an accusation against Mr Mellish in the course of her evidence, but she admitted that she had said nothing at the time of the alleged offence Mr Justice Jelf pointed out that no man had any right to take the law into his own hands There were however horsewhippings and horsewhippings The jury must do their duty according to law but after they had done this they were at liberty to show that the plaintiff had only received a richly deserved castigation The jury found a verdict for the plaintiff with one farthing damages The defendant paid 1s into court and was awarded judgment with costs The judge in conclusion said that an unfair aspersion had been needlessly made upon the defendant in the course of the trial Such an attack was especially likely to damage a medical man but it had utterly failed Mr Mellish's reputation was untouched It was quite right that there should have been a special jury and he certified accordingly We congratulate Mr Mellish upon the happy ending to this case. An accusation such as was made against him, though such accusation was not the point of the case is easy to make and hard to refute and it is well to have had the matter so thoroughly inquired into in a public court.

MEDICAL TESTIMONIALS TO QUACKERY

In *Pearson's Magazine* for February 1903 appears an advertisement of a quack preparation known as bile beans Its harmlessness and usefulness are guaranteed by two testimonials purporting to come from medical men One is dated from 65 Regent-street London, W and is signed J H Hart L R C P and L R C S We cannot find Mr J H Hart's name in the Medical Register, and although he alleges that he has examined samples of bile beans and certifies that they are composed of selected high-class preparations we do not think that his qualifications are those of a skilled analytical chemist and moreover 65 Regent-street is a confectioner's shop The other testimonial is dated from 9 Guildford street Russell square and is signed C H. Bennett L R C.P and L.R C S The name C H. Bennett with the qualifications of L R C.P L R C S Edin appears in the Medical Directory as that of a practitioner living in the provinces whose address is uncommunicated. No 9 Guildford street is according to the Post Office Directory a lodging house and as regards Mr Bennett's analysis we can only repeat what we have already said about that of Mr Hart We think that the attention of the General Medical Council might well be called to the act of these two members of the profession We would further intimate to the proprietors of popular magazines that they are taking dirty money by inserting the numerous advertisements which they do insert emanating from quacks

A WARNING

To the Editors of THE LANCET

SIRS —On Feb. 19th a German representing himself as a Dr Osten an M.D of Berlin and now a student at the London Hospital presented himself at the North West London Hospital professing to be interested in medical work In accordance with continental etiquette I gave him my card The same evening he called at my private residence and, after fully apologising for his untimely visit on so short acquaintance, wished to borrow some ready cash. I explained that I never lent money but was willing to make him a small gift which I did I have since heard that when this so-called Doctor left the hospital property belonging to the house surgeon left it too I feel it my duty to warn the profession against this individual as I fear he may make use of my card as an introduction

I am Sirs yours faithfully,

W KNOWSLEY SIBLEY M.D Cantab

Duke-street Mansions W Feb 23rd 1903.

*** The Warden of the London Hospital Medical College informs us that there is no such person as Dr Osten connected with the London Hospital or Medical College A person describing himself as Dr Osten has had some letters addressed to the London Hospital but the Warden having heard that Dr Osten was obtaining money under false pretences informed the police of the matter Since then nothing has been seen within the hospital of Dr Osten. —ED L

◆

Young Practitioner —To use a nurse as an unqualified assistant is a professional offence If such conduct can be proved against a practitioner the General Medical Council should certainly order him to desist or to run the risk of losing his place on the Register It would be a more difficult task to convict a medical man of having an agreement with a parish nurse and we are loth to believe in these irregular bonds between practitioners and nurses

Candid Jane —The eminent doctors who discuss or who are said to have discussed these topics with ill informed paragraph writers are not, as a rule people of any standing in the medical profession and are frequently not medical men at all The specific instances bear the trace of pure invention while the writer's own contribution to scientific knowledge shows complete ignorance of anatomy, physiology, and medical procedure

A S W —Many methods have been employed for the removal of tattoo marks but very few of them are of value. The three chief methods are 1 Cauterisation of the part or scarification leading to the formation of a scar 2. Excision, the edges of the wound being brought together, this is possible only for small areas and where the skin is loose 3. Excision followed by Thiersch grafting

X —We do not know any place where such forms are kept but any solicitor if the conditions are explained to him ought to be able to embody them in an agreement

Yorks —Our correspondent is advised to communicate with the secretary of the Pharmaceutical Society of Great Britain 17 Bloomsbury square London W C

F W L —We do not know the name of any insurance company making the provision mentioned Lloyds" are said to take these risks

Medical Diary for the ensuing Week.

OPERATIONS

METROPOLITAN HOSPITALS

MONDAY (2nd) —London (2 P M) St. Bartholomew's (1.30 P.M) St. Thomas's (3 30 P.M) St. George's (2 P.M) St. Mary's (2.30 P M), Middlesex (1.30 P.M) Westminster (2 P M), Chelsea (2 P.M.), Samaritan (Gynæcological by Physicians 2 P.M.) SOCIETIES

MONDAY (2nd) —MEDICAL SOCIETY OF LONDON (11 Chandos-street, Cavendish square W) —9 P M. Dr H. Radcliffe Crocker: The Conditions which Modify the Characters of Inflammations of the Skin, and their Influence on Treatment Lecture II —General Modifying Conditions (Lettsomian Lecture.)

TUESDAY (3rd) — PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square W) —Dr Herringham and Dr Hurtley: On the Excretion of Alkalies in Certain Conditions of Renal Disease —Mr H. W Armit On Ehrlich's Dimethyl (p) Amido benzaldehyde Reaction.—Dr O K. Williamson On the Relation existing between Uric Acid Excretion and the Breaking Down of White Blood Corpuscles.

WEDNESDAY (4th) —OBSTETRICAL SOCIETY OF LONDON (20 Hanover-square, W).—8 P.M. Specimens will be shown by Dr Blacker Dr H. Roberts, Dr Lewers Dr Tate Dr A. Routh Dr Handfield Jones and Mr Bland Sutton. Inaugural Address:—Dr Malins (President): Some Aspects of the Economic and of the Antenatal Waste of Life in Nature and Civilisation

THURSDAY (5th) —HARVEIAN SOCIETY OF LONDON (Stafford Rooms Titchborne-street, Edgware-road, W) —8.30 P.M. Papers:—Mr P L. Mummery: The Value of Arthrotomy in the Treatment of Certain Joint Lesions.—Dr Sidney Phillips.

NORTH EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N) —4 P.M. Paper:—Dr F J Tresilian Some of the Vagaries of Syphilis.

RÖNTGEN SOCIETY (20 Hanover-square, W) —8.30 P.M. Paper —Mr F H Glew Spark Phenomena.

FRIDAY (6th) —WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary Greenwich-road S.E.).—8.45 P.M. Cases will be shown by Dr M. Dockrell Mr C Ryall, Dr F S Toogood Mr C Williams and Dr R. E Scholfield.

SOCIETY OF ANÆSTHETISTS (20 Hanover-square W) —8.30 P.M. Papers —Mr A. V Harcourt New Chloroform Regulating Inhaler by which the Percentage of Chloroform in the Vapour Inhaled can be Positively Controlled. (The instrument will be shown.)

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover-square, W) —5 P.M. Cases Specimens and Instruments will be shown by Mr F J Steward, Mr C Baber Dr Tilley Dr Kelson Dr Bronner and others

SATURDAY (7th).—MEDICAL SOCIETY OF LONDON (Whitehall Rooms Hôtel Metropole) —7.30 P.M 130th Anniversary Dinner

LECTURES ADDRESSES DEMONSTRATIONS &c

MONDAY (2nd) —ROYAL COLLEGE OF SURGEONS OF ENGLAND —5 P.M. Prof A. Keith: A Research into the manner in which the Abdominal Viscera are maintained in Position in Man and in Animals allied to Man with a view of elucidating the condition usually described as Glenard's Disease."

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street W C) —4 P.M. Dr C Fox: Clinique. (Skin.) 5 15 P.M. Dr P H Pye-Smith: Albuminuria.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road W) —5 P.M. Mr Lloyd: Anæsthetics in Cases of Empyema, &c.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street W) —5 P.M General Monthly Meeting

TUESDAY (3rd) —MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C) —4 P.M. Dr C O Hawthorne Clinique. (Medical.) 5.15 P.M. Mr E Clarke Defects of Refraction.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W) —5 P.M. Dr Moullin Posterior Displacement of the Uterus

UNIVERSITY OF LONDON (Physiological Laboratory) —5 P.M. Dr W D Halliburton: On the Chemistry of Muscle and Nerve. (Lecture on Advanced Physiology)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square, Bloomsbury) —3.30 P.M. Dr Buzzard On Cases in the Wards.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street W) —5 P.M. Sir W Abney Recent Advances in Photographic Science.

WEDNESDAY (4th) —ROYAL COLLEGE OF SURGEONS OF ENGLAND —5 P.M. Prof A. Keith A Research into the manner in which the Abdominal Viscera are maintained in Position in Man and in Animals allied to man with a view of elucidating the condition usually described as Glenard's Disease."

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C) —4 P.M. Mr J Smith: Clinique. (Surgical.) 5.15 P.M. Mr A. Carless The Systematic Examination of Joints in Disease and Injury

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W) —5 P.M. Dr S Taylor Diagnosis and Treatment of Valvular Disease of the Heart

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton) —4 P.M Dr Acland: Pneumothorax.

THURSDAY (5th) —ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East) —5 P M. Dr H. T Bulstrode: The Causes Prevalence, and Control of Tuberculosis (Milroy Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street W C) —4 P.M. Mr W H. A. Jacobson: Clinique. (Surgical.) 5 15 P.M. Dr G H Savage Insanity of Decay

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W) —5 P.M. Mr Edwards: Rectal Stenosis.

UNIVERSITY OF LONDON (Physiological Laboratory) —5 P.M Dr T G Brodie: On the Circulation. (Lecture on Advanced Physiology)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W C) —4 P.M. Dr F E Batten: Deformities of the Chest in Children.

CHARING CROSS HOSPITAL.—4 P.M. Dr Galloway: Dermatological Demonstration. (Post-Graduate Course.)

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W) —5 P.M. Prof. L. C Miall Insect Contrivances.

FRIDAY (6th) —ROYAL COLLEGE OF SURGEONS OF ENGLAND —5 P.M. Prof. A. Keith: A Research into the manner in which the Abdominal Viscera are maintained in Position in Man and in Animals allied to Man with a view of elucidating the condition usually described as Glenard's Disease."

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street W C) —4 P.M. Dr W J Horne Clinique. (Throat.) 5.15 P.M Mr H. L. Barnard: Acute Appendicitis.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W) —5 P M Dr R Jones: General Paralysis of the Insane and the Legal Aspects of Insanity

UNIVERSITY OF LONDON (Physiological Laboratory) —5 P.M. Dr A. D Waller: On the Action of Anæsthetics and Narcotics. (Lecture on Advanced Physiology)

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle street, W) —9 P M Dr J G McKendrick: Studies in Experimental Phonetics.

SATURDAY (7th).—ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle street W) —3 P.M. Right Hon. Lord Rayleigh: Light, its Origin and Nature.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. II. of 1902, which was completed with the issue of Dec 27th, and the Title-page to the Volume, were given in THE LANCET of Jan 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half-year's numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423 Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The Hunterian Lectures
ON
THE NATURE AND ANATOMY OF ENTEROPTOSIS (GLÉNARD'S DISEASE)

Delivered before the Royal College of Surgeons of England on March 2nd, 4th, and 6th 1903

By ARTHUR KEITH, M D Aberd,
F R C S Eng,
HUNTERIAN PROFESSOR ROYAL COLLEGE OF SURGEONS OF ENGLAND ETC

LECTURE I

Delivered on March 2nd.

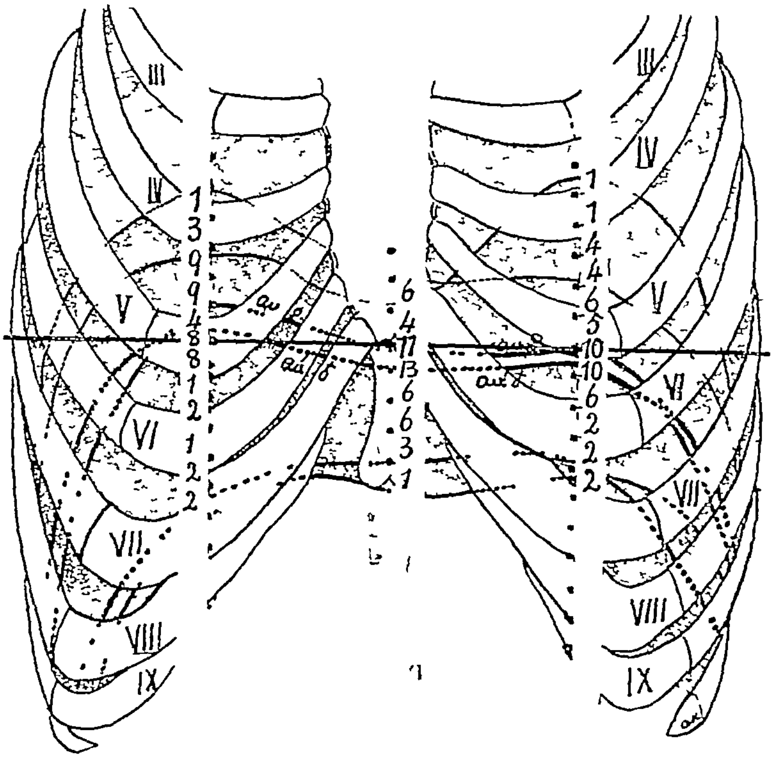
The Importance of the Respiratory Movements of the Abdominal and Thoracic Viscera.

Mr. President and Gentlemen,—Few medical men, as they follow the respiratory heave and fall in a patient's body, attempt to form an accurate conception of the movements of the viscera within the cavities of the thorax and abdomen They may know well that the heart, the liver, the stomach, the spleen, the kidneys, and the intestine go through a definite respiratory cycle with each breath, yet as these movements are but secondary to the expansion of the lung they are deemed of little importance within the field of practical medicine. My aim in the lectures which I have now the honour to deliver is to show (1) that a knowledge of the respiratory movements of the viscera gives the key to the manner in which they are fixed and placed within the body, and (2) that with any marked deviation in the action of the muscles of respiration there is a disturbance in the visceral movements, resulting in displacement and disorganisation of function

The nature of enteroptosis—The organs within the thoracic and abdominal cavities are poised between the muscles of inspiration and expiration, two contending sets which throughout the life of the individual, strive for the mastery There is in modern teaching a tendency to emphasise the respiratory importance of the walls of the thorax and to minimise the action of those of the abdomen Yet the structure of air breathing animals teaches very emphatically that the muscular wall of the entire trunk, from the upper aperture of the thorax to the floor of the perineum, is designed to increase and to diminish the ever fluctuating respiratory capacity of the body cavity The tendency to regard the thoracic as the chief respiratory part of the mammalian trunk is probably due to an erroneous conception of the action of the diaphragm The diaphragm, it is true separates the thoracic from the abdominal cavity, but its appearance within the mammalian body did not in any way relieve the muscles of the wall of the belly of their expiratory function Quite the reverse, the diaphragm is an ingenious addition to the inspiratory group of muscles and its evolution entailed an increased development of the muscles of the belly wall. Every organ within the body cavity swings with the respiratory tide. With each breath taken the ordinary muscles of inspiration—the external intercostals, the intercartilagines (intercostals between the costal cartilages), and the diaphragm—enlarge the body walls and displace the viscera, with each breath given the internal intercostals, the transversalis, the external and internal oblique muscles, and the rectus abdominis replace the viscera. In the majority of people the respiratory ebb and flow are so finely adjusted that at the end of life the viscera are poised much as they were in youth. Yet in the lifetime of a very considerable proportion of men and women circumstances over which they may, or may not, have control arise and upset the balance between the inspiratory and expiratory groups of muscles. In such cases it is, with the exception of emphysematous conditions, the muscles of inspiration that gain the upper hand and the muscles of expiration that yield When the respiratory balance is upset the viscera, not only of the abdomen, but also of the thorax, are displaced downwards and the condition of *enteroptosis* is produced Thus enteroptosis is the result of a vitiated method of respiration and should be assigned really to the respiratory diseases. It sometimes happens that the incidence of the disease falls particularly on one organ, very frequently the kidney, sometimes the stomach, liver, or spleen. In such cases, although one organ has suffered the chief attack of the inspiratory force, yet a full examination will show that all are displaced although to a less degree.

The variable position of the diaphragm.—Every body opened in the dissecting room shows, by the position of its viscera the result of a life long contest between the two opposing sets of respiratory muscles. The diaphragm, which forms the roof of the abdominal cavity, rests like a muscular hood on the abdominal viscera Three points in it—viz., the highest point of the right dome the highest point of the left dome, which usually occur in the right and left mammary lines, and the part of its central tendon on which the heart rests, may be taken as representing the upper level of the abdominal viscera. In *Fig* 1 are set forth diagrammatically the variations of the upper level of the abdominal viscera, observed in 50 subjects. On an

Fig 1.



A diagram showing the position of the diaphragm in 50 subjects (35 male and 15 female) Tracings of the two highest and the two lowest diaphragms are represented; the two intermediate tracings give the average position for the male (lower) and female (upper) The xiphisternal joint was taken as the level from which vertical measurements were made. Centimetre points are represented in the middle and each mammary line. The middle and lateral vertical rows of figures represent the number *of cases* occurring in each centimetre.

average the domes of the diaphragm and the abdominal viscera which fill them lie just behind the upper border of the fifth costal cartilage in the mammary line and the central tendon one third of an inch below the junction of the ensiform process and sternum. There is a wide and constant fluctuation from these average points. The domes may rise above the third costal cartilage or lie below the sixth, the central tendon may rest behind the sternum, an inch or more above the average point, or it may fall as low as the extremity of the ensiform process. Thus there is a range of over three and a half inches in the level of the domes and more than two inches in the central tendon of the diaphragm The extensive fluctuation in the position of the diaphragm shown in Fig 1 is due, to some extent at least, to the fact that the subjects on which it is founded varied widely in age The series of bodies on which this figure is constructed includes 40 which were examined and very accurately recorded in a memoir by a predecessor in this chair, Professor C Addison[1], his observations deal with 28 men and 12 women, varying in age from 13 to 71 years. The dissecting room subjects, including seven men and three women, which I have added to make up a series of 50, were aged individuals to whom nature had sternly debited to their old age the profligacy of their youth. Thus the fluctuation in the position of the diaphragm shown in Fig 1 must be regarded as an exaggeration of the condition to be found in an equal series of healthy subjects in the prime of life. Seven female subjects, included in the following tables, were examined after the diagram given in Fig 1 was prepared On an average the position of the female diaphragm is slightly higher than that of the male (see Fig 1) As may be seen from Table I the range of variation is rather greater in the male than in the female and on the right side than on the left[2]

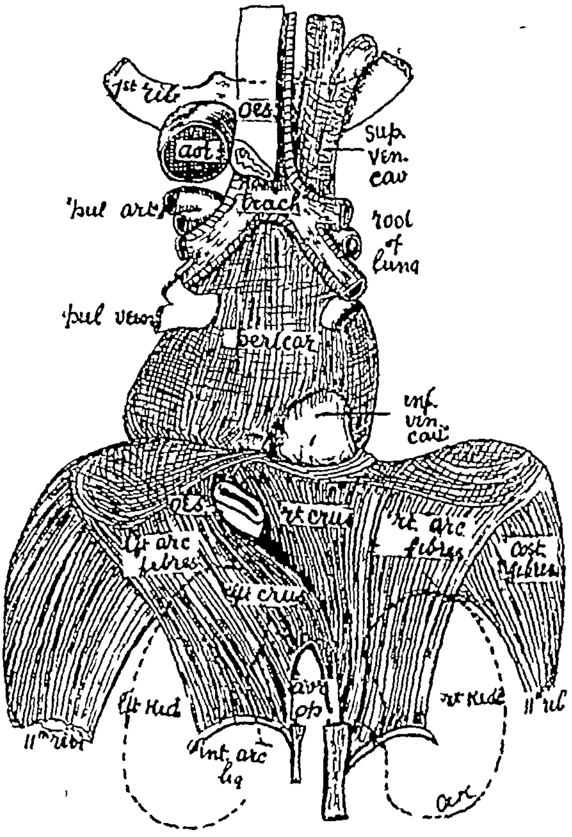
The variations in the level of the diaphragm represent the phases of its respiratory cycle —Those who have watched the movements of the diaphragm in the living body by the aid of the Roentgen rays will be struck by the resemblance of Fig 1 to a diagram representing the various phases through which the diaphragm passes in a complete respiratory movement of the abdominal type The diaphragm after death when rigor mortis is gone, represents a phase of complete expiration, the elasticity of the lungs insures the contraction of the pleural cavities to their utmost physiological extent It is evident, then, that of the subjects represented in Fig 1 the position of complete inspiration of those highest in the series corresponds in position to the phase in complete expiration in those the lowest in the series Yet all started off alike at birth In the full time child the central tendon of the diaphragm hardly varies in position, it lies at the level of a line drawn from the sternal end of the sixth costal cartilage to the disc between the eighth and the ninth dorsal vertebræ For some reason the supports of the diaphragm give way in certain individuals, but at what degree of displacement a marked impairment of its action and disorganisation of the function of the abdominal viscera take place it is difficult to define with exactitude, the physiological limits are so wide. There can be no doubt, however, that in the six cases (three males and three females) in which the domes of the diaphragm were situated below the level of the lowest part of the sixth costal cartilage and the central tendon on a level with the lower end of the ensiform process, were cases in which the action of the diaphragm was markedly impaired and the function of the viscera disorganised and that they were therefore true cases of enteroptosis The disease must be judged not by the extent of displacement but by the degree of distress

The supports of the diaphragm —Since the downward displacement of the diaphragm is an essential feature of all cases of ptosis of the viscera the manner in which it is supported and maintained in position is naturally the first point to be settled. Besides, the liver, spleen, stomach, and kidneys are firmly bound to its abdominal aspect The means of diaphragmatic support are three in number—viz. (1) abdominal, (2) thoracic, and (3) costal. The *abdominal* support is supplied by the muscles of expiration, mainly by those of the abdominal wall which keep the abdominal contents pressed within the concavities of the diaphragm The *thoracic* support is provided by the pericardium, the heart, and the great vessels and lungs which directly or indirectly attach the upper surface of the diaphragm to the structures at the root of the neck and to the whole extent of the thoracic wall The *costal* support is given by the abdominal ends of the lower six ribs, long moveable levers, maintained in position by their passive articulations with the spine and

FIG 2



The attachments of the crura and arcuate fibres of the diaphragm to the inferior vena cava and pericardium (From a dissection made after removal of the spinal column) the active contraction of the external intercostal sheet of muscles. Each of the three supports is necessary for the maintenance of the diaphragm in position, a partial collapse of one is followed by a corresponding failure of the other two Hence it is that in well marked cases of enteroptosis the chest is deformed, the thoracic viscera occupy abnormal positions, and the contents of the abdomen are displaced.

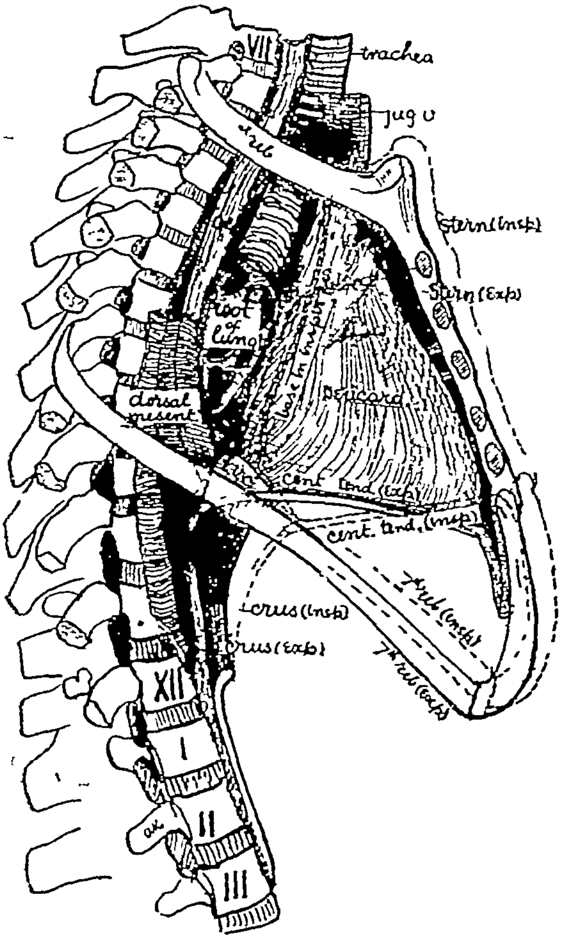
[2] I take this opportunity of acknowledging my indebtedness to the following papers: Les Ptoses Viscerales by Dr Frantz Glenard Ueber die Athembewegungen des Menschlichen Körpers, by Professor C Hasse of Breslau Archiv für Anatomie und Physiologische Anatomie Abtheile 1901 Die Entwickelung der Athemmechanik im Kindesalter by Dr Konrad Gregor Anatomischer Anzeiger Band xxii p 119 1902 The Anatomy of the Intestinal Canal and Peritoneum Hunterian Lectures by Sir Frederick Treves 1885 On the Development of the Great Omentum and Transverse Colon by C B Lockwood Proceedings of the Royal Society of London vol xxxv 1883

The mobility of the central or interpleural area of the diaphragm.—In the past I have followed the lead of the majority and taught that the part of the diaphragm between the pleuræ on which the heart rests and which the inferior vena cava, the œsophagus, and the aorta perforate was nearly immoveable and of little respiratory importance. Holding this conception, it was always a difficult matter to explain satisfactorily why the fibres of the two crura constituting rather more than a fifth of the total muscle, should ascend vertically to be attached to the cardiac area of the diaphragm (See Fig 2) The pericardium and the strongly ensheathed inferior vena cava, being intimately adherent to this area, prolong the insertion of the crural fibres to all the structures of the mediastinum but especially to three parts (1) to the heart itself, (2) to the roots of the lungs, and (3) to the great vessels and fibrous tissue in the upper aperture of the thorax. (See Fig 3.) Thus with each inspiration the crura, from a firm spinal origin, exert their strength in drawing downwards the structures of the mediastinum and thus drawing down the supports on which the central part of the diaphragm depends. The active contraction of the crura is the most important factor in the production of the condition of visceral ptosis

FIG 3



Contents of the thorax seen from the right lateral aspect to show the attachment of the crus to the inferior vena cava and pericardium and indirectly to the roots of the lung The parts are represented at the *end of expiration* The position of the crus central tendon, seventh rib, and sternum at the *end of inspiration* are represented by stippled lines.

The movements of the mediastinal structures—To appreciate fully the action of the crural fibres it is necessary to turn aside for a minute and to consider the normal respiratory movements of the central part of the diaphragm and mediastinal structures When the body is viewed in profile, the mediastinal structures are seen to occupy a well marked triangle. (See Fig 3) The base of this mediastinal triangle is formed by the greater part of the central leaflet of the diaphragm, the sternum forms its anterior boundary, and the superior vena cava, auricular base of the heart, and inferior vena cava form its posterior wall. In the posterior boundary are fixed the roots of the lungs The apex of the triangle is attached to the upper aperture of the thorax. When a breath is taken the mediastinal triangle and its contents swing forwards from the spine. Its posterior boundary, which slopes downward and backward at the commencement becomes nearly vertical at the end of the inspiratory swing while the anterior or sternal boundary, rising upwards and forwards, becomes more oblique.

To understand the pendulum like movement of the mediastinal contents the following anatomical points have to be noted 1 The upward and forward movement of the sternal boundary of the triangle is due to the contraction of two strong sheets of muscle—the external intercostals and inter-cartilagines, by elevating the ribs and costal cartilages they throw the sternum upwards and forwards 2 The base of the mediastinal triangle, being bound to the ensiform process and seventh costal cartilages must follow the forward and upward movements of the sternum. 3. The attachment of the crura to the posterior margin of the base drags that part of the base and the posterior contents of the triangle downwards during the forward movement 4 That the forward movement of the mediastinal triangle may take place the contents of the mediastinum—the œsophagus, trachea, and heart—are bound loosely to the dorsal region of the spine by a mesentery[3] formed by the posterior reflections of the mediastinal pleuræ (see Fig 3) Thus, the dorsal mesentery of the thorax, undergoes an extension forwards with each breath.

Estimation of the mediastinal movements—Thanks to the introduction of the Roentgen rays the mediastinal movements, at first inferred from a consideration of the anatomical arrangements in the dead, can be verified and studied in the living Turning a patient sideways to the tube, so that the rays enter in front of the lower angle of the left scapula and emerge behind that of the right the base of the heart, when a deep breath is taken, can be seen to move forwards and downwards from the spine, leaving the posterior mediastinum a gleaming window behind it The extent and direction of the movements vary with the type of respiration, but in a subject in whom the abdominal and thoracic respiratory movements are about equally developed the diagonal movement of the base of the heart, allowing for magnification of the image on the screen, varies from one and a half to two and a half inches in a complete inspiration In abdominal breathers not only is the range of movement greatest but the downward displacement of the diaphragm and viscera is also much more marked The inspiratory downward displacement, if once the diaphragmatic supports commence to yield, is one of the factors in the causation of visceral ptosis

The adhesion of the base of the pericardium to the diaphragm in man.—The adhesion of the pericardium to the diaphragm in man is now recognised as an adaptation to his upright or orthograde posture. It serves as a most effective support against ptosis of the viscera In the anthropoids, which also are orthogrades, the same extensive pericardial attachment is to be seen The adaptation is peculiar in this that it is a relapse to a more primitive condition During the embryonic development of all mammals the base of the pericardium and central tendon of the diaphragm are fused, but in all mammals except those adapted to the orthograde posture, the two become separated as the lungs develop A lobe of the right lung the *lobus azygos*, a vestige of which is present in man, expands and collapses with each breath between the pericardium and central tendon. Thus in pronograde mammals the central as well as the lateral parts of the average the domes of the diaphragm and the abdominal viscera which fill them lie just behind the upper border of the fifth costal cartilage in the mammary line and the central tendon one third of an inch below the junction of the ensiform process and sternum There is a wide and constant fluctuation from these average points The domes may rise above the third costal cartilage or lie below the sixth, the central tendon may rest behind the sternum, an inch or more above the average point, or it may fall as low as the extremity of the ensiform process Thus there is a range of over three and a half inches in the level of the domes and more than two inches in the central tendon of the diaphragm. The extensive fluctuation in the position of the diaphragm shown in Fig 1 is due, to some extent at least, to the fact that the subjects on which it is founded varied widely in age The series of bodies on which this figure is constructed includes 40 which were examined and very accurately recorded in a memoir by a predecessor in this chair, Professor C Addison[1], his observations deal with 28 men and 12 women, varying in age from 13 to 71 years. The dissecting room subjects, including seven men and three women, which I have added to make up a series of 50, were aged individuals to whom nature had sternly debited to their old age the profligacy of their youth. Thus the fluctuation in the position of the diaphragm shown in Fig 1 must be regarded as an exaggeration of the condition to be found in an equal series of healthy subjects in the prime of life. Seven female subjects, included in the following tables, were examined after the diagram given in Fig 1 was prepared On an average the position of the female diaphragm is slightly higher than that of the male (see Fig 1) As may be seen from Table I the range of variation is rather greater in the male than in the female and on the right side than on the left[2]

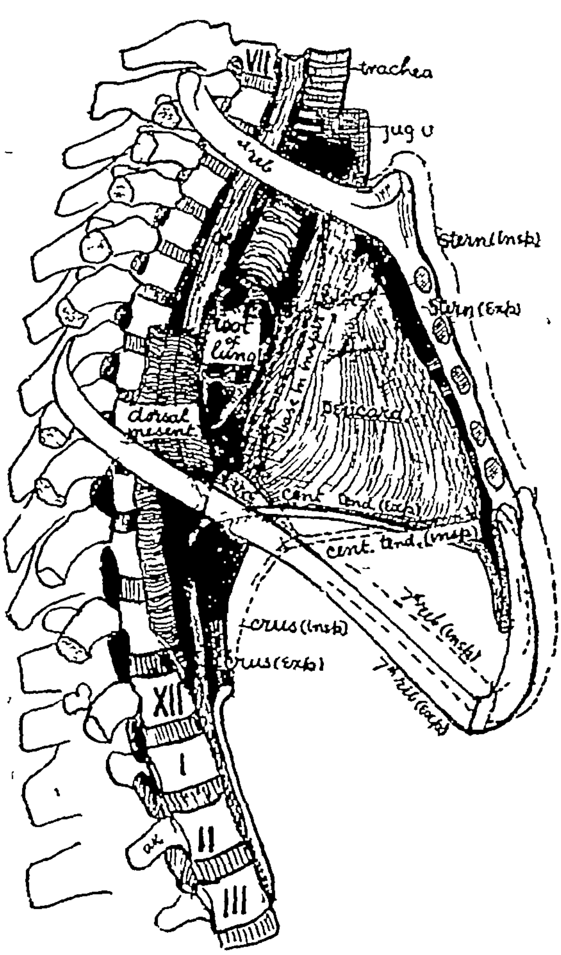
[2] I take this opportunity of acknowledging my indebtedness to the following papers: Les Ptoses Viscérales by Dr Frantz Glenard Ueber die Athembewegungen des Menschlichen Körpers by Professor C Hasse of Breslau Archiv für Anatomie und Physiologische Anatomie, Abtheile 1901 Die Entwickelung der Athemmechanik in Kindesalter by Dr Konrad Gregor Anatomischer Anzeiger Band xxii p 119 1902 The Anatomy of the Intestinal Canal and Peritoneum Hunterian Lectures by Sir Frederick Treves 1885 On the Development of the Great Omentum and Transverse Colon by C B Lockwood Proceedings of the Royal Society of London vol xxxv 1883

he active contraction of the external intercostal sheet of nuscles. Each of the three supports is necessary for the naintenance of the diaphragm in position, a partial ollapse of one is followed by a corresponding failure of he other two. Hence it is that in well marked cases of nteroptosis the chest is deformed, the thoracic viscera ccupy abnormal positions, and the contents of the abdomen re displaced.

The mobility of the central or interpleural area of the diaphragm.—In the past I have followed the lead of the majority and taught that the part of the diaphragm between the pleuræ on which the heart rests and which the inferior vena cava, the œsophagus, and the aorta perforate was nearly immoveable and of little respiratory importance. Holding this conception, it was always a difficult matter to explain satisfactorily why the fibres of the two crura, constituting rather more than a fifth of the total muscle, should ascend vertically to be attached to the cardiac area of the diaphragm (See Fig 2) The pericardium and the strongly ensheathed inferior vena cava, being intimately adherent to this area, prolong the insertion of the crural fibres to all the structures of the mediastinum but especially to three parts (1) to the heart itself, (2) to the roots of the lungs, and (3) to the great vessels and fibrous tissue in the upper aperture of the thorax. (See Fig 3.) Thus with each inspiration the crura from a firm spinal origin, exert their strength in drawing downwards the structures of the mediastinum and thus drawing down the supports on which the central part of the diaphragm depends. The active contraction of the crura is the most important factor in the production of the condition of visceral ptosis.

FIG 3



Contents of the thorax seen from the right lateral aspect to show the attachment of the crus to the inferior vena cava and pericardium and indirectly to the roots of the lung The parts are represented at the end of expiration The position of the crus central tendon, seventh rib and sternum at the end of inspiration are represented by stippled lines.

The movements of the mediastinal structures—To appreciate fully the action of the crural fibres it is necessary to turn aside for a minute and to consider the normal respiratory movements of the central part of the diaphragm and mediastinal structures When the body is viewed in profile the mediastinal structures are seen to occupy a well marked triangle (See Fig 3) The base of this mediastinal triangle is formed by the greater part of the central leaflet of the diaphragm, the sternum forms its anterior boundary, and the superior vena cava, auricular base of the heart, and inferior vena cava form its posterior wall. In the posterior boundary are fixed the roots of the lungs The apex of the triangle is attached to the upper aperture of the thorax. When a breath is taken the mediastinal triangle and its contents swing forwards from the spine. Its posterior boundary, which slopes downward and backward at the commencement, becomes nearly vertical at the end of the inspiratory swing, while the anterior or sternal boundary, rising upwards and forwards, becomes more oblique.

To understand the pendulum like movement of the mediastinal contents the following anatomical points have to be noted 1 The upward and forward movement of the sternal boundary of the triangle is due to the contraction of two strong sheets of muscle—the external intercostals and inter cartilagines, by elevating the ribs and costal cartilages they throw the sternum upwards and forwards 2 The base of the mediastinal triangle, being bound to the ensiform process and seventh costal cartilages must follow the forward and upward movements of the sternum. 3. The attachment of the crura to the posterior margin of the base drags that part of the base and the posterior contents of the triangle downwards during the forward movement 4 That the forward movement of the mediastinal triangle may take place the contents of the mediastinum—the œsophagus trachea and heart—are bound loosely to the dorsal region of the spine by a mesentery[3] formed by the posterior reflections of the mediastinal pleuræ (see Fig 3) This, the dorsal mesentery of the thorax, undergoes an extension forwards with each breath.

Estimation of the mediastinal movements—Thanks to the introduction of the Roentgen rays the mediastinal movements, at first inferred from a consideration of the anatomical arrangements in the dead, can be verified and studied in the living Turning a patient sideways to the tube, so that the rays enter in front of the lower angle of the left scapula and emerge behind that of the right the base of the heart, when a deep breath is taken, can be seen to move forwards and downwards from the spine, leaving the posterior mediastinum a gleaming window behind it The extent and direction of the movements vary with the type of respiration but in a subject in whom the abdominal and thoracic respiratory movements are about equally developed the diagonal movement of the base of the heart allowing for magnification of the image on the screen, varies from one and a half to two and a half inches in a complete inspiration In abdominal breathers not only is the range of movement greatest but the downward displacement of the diaphragm and viscera is also much more marked The inspiratory downward displacement, if once the diaphragmatic supports commence to yield, is one of the factors in the causation of visceral ptosis

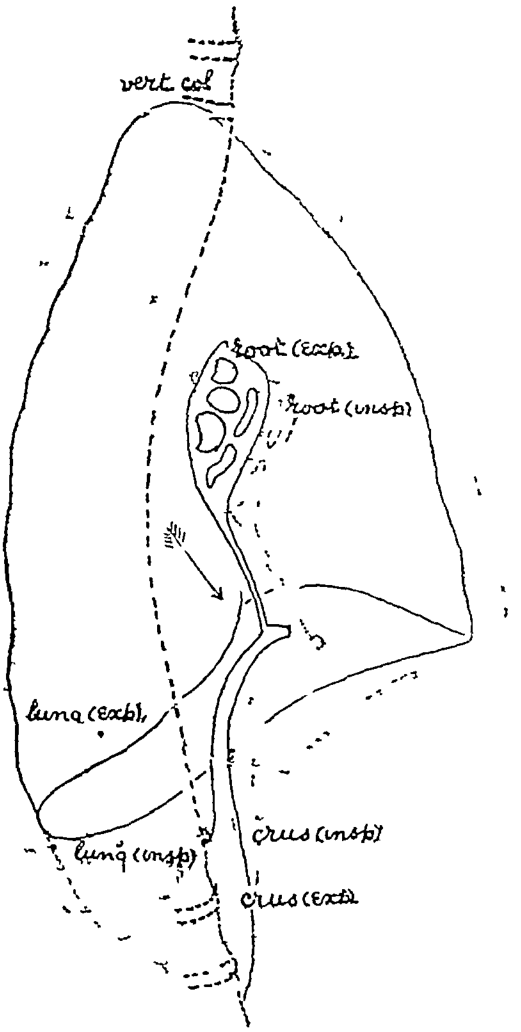
The adhesion of the base of the pericardium to the diaphragm in man.—The adhesion of the pericardium to the diaphragm in man is now recognised as an adaptation to his upright or orthograde posture. It serves as a most effective support against ptosis of the viscera In the anthropoids, which also are orthogrades, the same extensive pericardial attachment is to be seen The adaptation is peculiar in this that it is a relapse to a more primitive condition During the embryonic development of all mammals the base of the pericardium and central tendon of the diaphragm are fused, but in all mammals except those adapted to the orthograde posture, the two become separated as the lungs develop A lobe of the right lung the *lobus azygos*, a vestige of which is present in man, expands and collapses with each breath between the pericardium and central tendon. Thus in pronograde mammals the central as well as the lateral parts of the diaphragm take a direct part in filling and emptying the lungs The adhesion of the pericardium to the diaphragm, with the evolution of the upright posture, far from diminishing the inspiratory load of the central part of the diaphragm, as might appear at first sight increases that load Instead of exercising its inspiratory effect directly on the lung the central part of the diaphragm produces it through the heart The heart is shaped so as to serve as a respiratory cone or plug, when drawn downwards and forwards by the crural fibres an inward expansion of the lungs occurs to occupy the space vacated by the heart. The crural fibres, as I have pointed out elsewhere,[4] probably also produce a direct effect on the heart and assist in the valvular mechanism round the termination of the great veins in the auricles

---

[3] This term may be correctly used The serous reflection is derived from the dorsal mesentery of the foregut

The attachment of the central part of the diaphragm to the roots of the lungs —The central part of the diaphragm being attached to the roots of the lungs through the pericardium it is evident that a contraction of the one must be accompanied by some degree of displacement in the other Why should the diaphragmatic crura be thus yoked to the roots of the lungs? The explanation is shown in Fig 4 When a breath is drawn the apex and posterior wall of the thorax take no part in the enlargement of the chest, the expansion takes place only in a downward, forward, and outward direction, necessitating a movement of the entire lung Were the roots of the lungs fixed such a movement would be greatly impeded. The centre of the lung, represented b the root, moves downwards and forwards with each brea to allow the lung to expand equally The crura of th diaphragm assist this movement the heart and lungs bein thus maintained in the same relative positions at all phase of the respiratory cycle The elasticity and extensibility c the trachea greatly facilitate the descent of the pulmonar roots

FIG 4



Showing the direction of the expansion of the lung It takes place only in a downward forward, and outward direction The root of the lung moves in a corresponding direction The stippled lines represent the anterior border of base, crus and root at the end of inspiration

Cervical curvature in visceral ptosis —In cases of viscera ptosis there is commonly a marked forward curvature in th cervical region of the spine—"ewe-neck," as Dr W Williams[5] names the condition An explanation of thi symptom will be found in the attachment of the structure of the mediastinum which support the central part of th diaphragm from the upper aperture of the thorax an structures in the root of the neck. The fibrous tissue whic ensheathes the pulmonary vessels and also the great venou and arterial trunks of the superior mediastinum and nec represents the strewn out remnants of the branchial arches it is really a direct upward continuation of the fibrou pericardium into the neck By this tissue the contents o the mediastinum are bound to the upper margin of th manubrium sterni, to the inner ends of the clavicles, t Sibson's fascia, to the first pair of ribs and anterior tubercle of the cervical transverse processes The first pair of ribs i cases of ptosis are not only oblique in position but are ofte bent downwards at the junction of the neck and body Th cervical curvature is probably due to a failure of the costal o abdominal supports of the diaphragm, whereby an increase strain is thrown on the mediastinal supports and by then transferred to the neck

The lungs as diaphragmatic supports —Collapse and dis placement of the domes of the diaphragm are the mos characteristic features of visceral ptosis and hence it i necessary to inquire into the structures which support them in the thorax. Rightly considered, the lungs themselves ar really conical elastic ligaments which bind the domes of the diaphragm to the whole extent of the costal wall Unless air or fluid is introduced into the pleural cavity the lung i bound by the pressure of an atmosphere to the diaphragm and thoracic parietes, hence to allow the domes to become permanently depressed either the lungs must become elongated or their elasticity lessened. A deformity of th chest which lessens the pulmonary space will lead to a downward displacement of the lungs and consequently o the domes of the diaphragm. The elasticity of the lung i greatly diminished in emphysema, but ptosis is prevente in such cases by the hypertrophy of the transversalis muscle of the abdomen

Summary of the thoracic supports of the diaphragm.—I will thus be seen that all the structures within the thorax the heart, the great vessels, the pericardium, the mediastina and cervical fasciæ the dorsal mesentery of the thorax, an the lungs, help to bind the diaphragm to the walls of th thorax and neck Each contraction of the diaphragm has to overcome the resistance offered by these structures to it contraction, the resistance it overcomes, which results in expansion of the lungs, may be termed the thoracic load o the diaphragm.

The structure and action of the diaphragm —Howev important the passive supports of the diaphragm may be i is the contraction of the muscle itself that is the activ factor in the production of displacement of viscera. Althoug one of the most important muscles of the body it i also one of the least understood. The traditional account of the diaphragm which has come down through th centuries to us as a muscle which takes its origin by series of fasciculi from the circumference of the body wal and converges to its central tendon like the spokes of wheel to the nave has done more to retard a true conceptio of the respiratory movements than any other circumstance. In structure, in development, in evolution, and in action th diaphragm is a true digastric muscle made up of tw segments, a spinal or dorsal and a costal or ventral. Th spinal segment consisting of crural and arcuate fibres (see Figs 2 and 5) takes a fixed origin from the last dorsal and upper three lumbar vertebræ and from the arcuate ligament thickenings of the sheaths of the psoas and quadratu lumborum muscles These spinal fibres, expanding as the ascend, terminate as fibrous strands in the central tendon from which most of the fibres of the costal segment directl

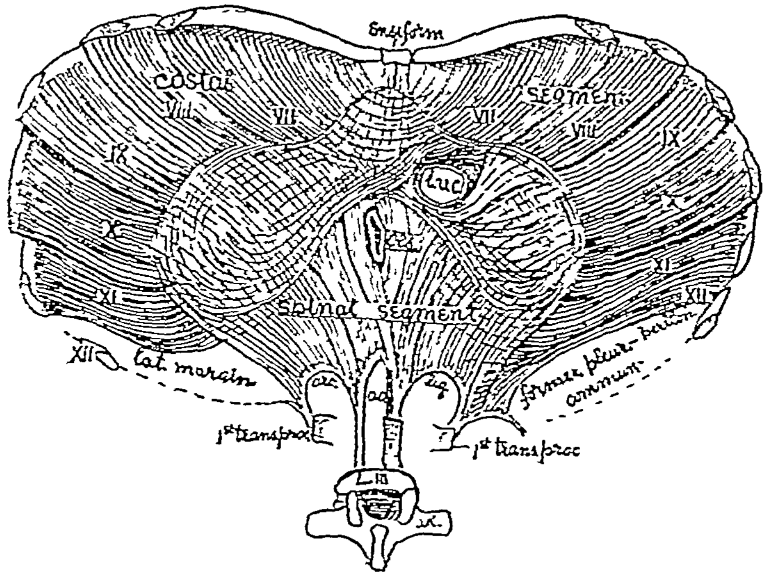
---

[4] Proceedings of the Anatomical Society of Great Britain and Ireland, November, 1902.

[5] Pathological Reports of the Royal Southern Hospital, Liverpool 1901

arise. (*See* Fig 5.) The costal fibres spread as they descend in front to their insertion on the abdominal or ventral ends of the lower six ribs but, as a rule, there is no insertion to the twelfth rib. The development of the arcuate fibres in man and in other orthograde primates has helped to obscure the true nature of the diaphragm. In "*four footed*" *or* pronograde primates only the crural fibres are present, but with the assumption of the orthograde posture the spinal segment of the muscle spreads outwards to the tip of the twelfth rib until the spinal origin and costal insertion of the muscle almost meet. At the same time, the insertion of the *quadratus lumborum*, a muscle which represents a backward continuation of the sheet from which the crural fibres of the diaphragm were developed also undergoes a corresponding extension outwards and thus binds the origin of the arcuate fibres to the ilium. In more than one half of the subjects which I have examined there was a fibrous interval between the origin and insertion of the diaphragm (See Figs 3 and 5) The interval marks the site of communication between the pleural and peritoneal cavities and the outer or lateral margin of the diaphragm With the evolution of the mammalia the outer edge of the diaphragm became fixed by fibrous tissue to the lateral costal wall and the pleural space separated from the peritoneal *Congenital diaphragmatic herniæ* occur between the lateral margin of the diaphragm and costal wall in such cases the free lateral margin of the diaphragm can be seen very distinctly

FIG 5.



The diaphragm spread out and viewed on its thoracic aspect. Fibres pass through the central tendon and unite the muscular fasciculi o the spinal segment to those of the costal segment.

LECTURE II.

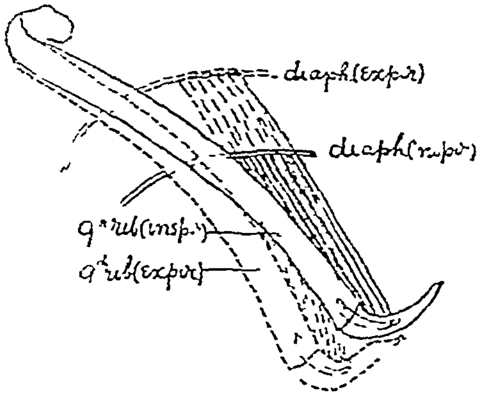
Delivered on March [illegible]th

The manner in which the diaphragm became a muscle of inspiration.—It is only in mammals that the diaphragm is inspiratory in action, the muscles which represent the spinal and costal segments in amphibians, reptiles, and birds assist in emptying the lungs. *In man, as in* mammals generally, were the contents of the abdominal cavity removed the diaphragm, by drawing the costal margin inwards in the direction of its origin from the lumbar spine, would diminish the body cavity and thus act as a muscle of expiration By the simple device of using the contents of the mammalian abdomen as a *respiratory* piston the diaphragm became one of the chief muscles of inspiration. This piston, pressed within the thorax by the muscles of the abdominal wall, carried in front of it the broad, fan shaped, double segmented diaphragm. It is this relationship to the abdominal viscera that gives the diaphragm its importance as a factor in the production of enteroptosis.

The movements of the abdominal contents in thoracic and abdominal types of respiration.—The effect which the diaphragm will exercise on the abdominal viscera on inspiration depends on two factors (1) the opposition offered by the muscles of the abdominal wall to the descent of the viscera, and (2) the mobility of the lower six ribs To the abdominal ends of these the costal fasciculi of the diaphragm are inserted If the muscles of the abdominal wall offer a strenuous opposition to the descent of the viscera then the abdominal contents are no longer a respiratory piston but a respiratory fulcrum over which the diaphragm is supported and from which it exerts its force on the points of insertion, the lower six ribs. By its contraction it tends to lift the whole thoracic cage off the abdominal fulcrum. The type of respiration is then said to be *thoracic*. If, on the other hand, the abdominal walls and viscera yield to the pressure of the diaphragm then the force of its contraction is spent, not in assisting the external intercostals in lifting up the thoracic cage, but in forcing down the abdominal viscera which become thus a respiratory piston. The type of respiration is then said to be *abdominal* Whether the type be thoracic or abdominal, in either case the effect of its contraction may lead to displacement of the abdominal viscera. If the visceral swing is greatest in the abdominal type the pressure to which the abdominal viscera are subjected is greatest in the thoracic type, but which of the two types is the more dangerous I cannot at the present tell.

The effect of displacements of the ribs on the action of the diaphragm.—In all circumstances, whether the type of respiration be abdominal or thoracic, or whether the ribs be normally *placed or not, the* action of the spinal segment of the diaphragm remains practically the same, it draws downwards the parts of the abdominal viscera attached to it. It is otherwise with the action of the costal segment. The direction in which the costal fibres act depends on the position of the ribs (Fig 6) If they are misplaced the action of the *fibres* are altered. The direction of a costal fasciculus of the diaphragm does not quite correspond to the axis of the rib on which it acts, although at the end of inspiration they are nearly identical In the expiratory phase the fasciculus to the ninth rib, for example, takes its origin from the central tendon on a level with the eighth rib or that for the tenth rib on a level with the ninth. But for all practical purposes the lower six ribs may be taken as

FIG 6.



Showing the relationship of the costal fibres to a rib at the end of inspiration and at the end of expiration (stippled).

indices of the axes in which the costal fibres of the diaphragm act. Hence when the ribs are at a small angle with the horizontal as they are in the child at birth (from 25° to 30°), the costal fibres, being arranged nearly in the axis of the rib, draw the viscera, which are within the concavity of the diaphragm, forwards against the anterior abdominal wall. In most mammals the horizontal (or in them vertical) position of the ribs is retained throughout life but in the course of growth the ribs of man become depressed from 10° to 20°, and come to occupy a position midway between the horizontal and vertical. The depression of the ribs is accompanied by a corresponding alteration in the direction of the costal fibres of the diaphragm. (Fig 6) These fibres then tend to push the viscera more downwards than forwards If the ribs be still further displaced, as they frequently are by the application of corsets or from disease, the action of the costal fibres of the diaphragm becomes still more vertical in the direction of their axis The more the fibres of the diaphragm tend to propel the viscera in a vertical direction the greater is the danger of visceral displacement.

The subcostal angle —At birth the subcostal angle, formed by the costal cartilages of the seventh and eighth ribs of one side with those of the other, measures about 90°, in the adult it becomes reduced to about 65° owing to the increased obliquity of the ribs In some cases of enteroptosis the subcostal angle measures 45° degrees or less, and in such cases the subject is usually female and under 45 years of age. On the other hand, enteroptosis in old people is accompanied by an opening out of the subcostal angle, in marked cases of displacement it measures from 90° to 95° It is very probable that the narrow angle of the younger cases becomes the wide angle in the older cases. The widening occurs and the displacement becomes more marked when, owing to the costal cartilages beginning to calcify, artificial supports of the body have to be undone or laid aside.

The development of the thoracic type of respiration.—The terms "thoracic" and "abdominal" certainly mislead many as to the true nature of the two types of respiration met with in human beings By "abdominal" is meant that type in which the pulmonary space is obtained mainly by an increase of the lower region of the thorax, by "thoracic" that in which it is gained mainly by an expansion of the upper region of the thorax. The abdominal is the mammalian type of respiration, and up to the seventh year, according to Dr Konrad Gregor[5] the human child retains this type. After the seventh year the muscles of the wall of the abdomen offer a greater resistance to an inspiratory descent of the viscera and the type of respiration becomes more thoracic. The alteration is more marked in girls than in boys, but in both sexes the types of respiration are mixed the thoracic preponderating in the female and the abdominal in the male.

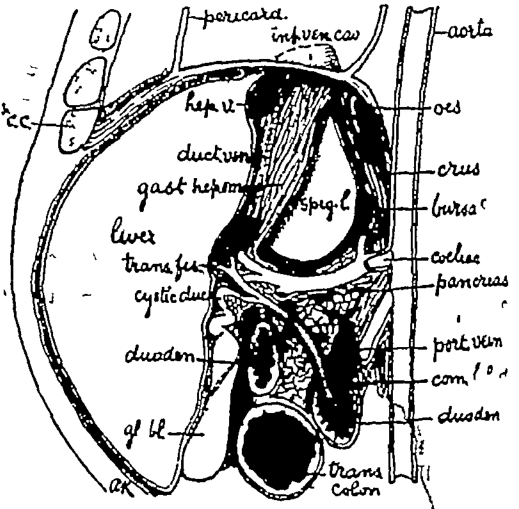
The visceral movements due to the action of the external intercostals and interchondrals —Were the diaphragm merely a fibrous, non muscular septum, the other muscles of inspiration, the external intercostals and interchondrals, by raising and enlarging the costal margin of the thorax would cause a movement of the abdominal viscera. The inspiratory movement of the costal margin besides raising the floor of the thorax, also increases the circumference of the diaphragm from one to four inches, according to the degree of inspiration The liver, stomach, spleen, and colon, in contact with the under surface of the diaphragm, undergo a corresponding change in shape and movement Thus, by their traction on the costal insertion of the diaphragm, the external intercostals assist that muscle in its inspiratory efforts

THE FIXATION AND MOVEMENTS OF THE ABDOMINAL VISCERA

Some years ago, when I began to pay special attention to the manner in which the viscera were retained in position, I undoubtedly attributed too much importance to the passive bonds which fix the viscera to the walls of the abdomen. In tracing the evolution of the upright posture through the various intermediate stages to be found in the living genera of primates I found that with each advance towards the orthograde posture the abdominal viscera became more extensively and more firmly fixed to the walls of the abdomen. The extensive fixation found adult man marks the culmination of the movement, in his embryonic and fœtal stages man repeats with ful accuracy the various conditions revealed by a study the primates Later I saw that, however interesting visceral bonds may be, they are of but minor importance the causation or prevention of enteroptosis in with the diaphragm. Having dealt with the fixation movements of the diaphragm, the manner in which abdominal organ is kept in position may now be described

Radix mesenterica —At only one small area of abdominal cavity are its contents immoveably fixed front of the twelfth dorsal and first lumbar verte between the origin of the crura of the diaphragm, the emerges from the dorsal mesentery of the thorax, cove with a strong fibrous coat, and gives off the two gr arterial trunks of the viscera—the cœliac axis and mesenteric artery (Fig 7) Here is the hilum of peritoneal cavity From the crura of the diaphragm sheath of the aorta strong fibrous and fibro muscular stream outwards on the arterial trunks of the liver, and intestine. Imbedded in the mass of fibrous each side of the origin of the arteries are the ganglia, the solar plexus streams out on the sheaths of the vessels Rich leashes of mesente phatics pass along the sheaths to reach the recep chyli between the aorta and right crus A speci muscular band (muscle of Treitz) leaves the lef often the right, to end in the duodeno-jejunal and to bind it to the fibrous mass In the fork b the cœliac axis and superior mesenteric artery is bound a segment of the body of the pancreas. Wha displacement may happen to the rest of the abd viscera the duodeno jejunal flexure and the part of pancreas just mentioned remain in position To the r the two arterial trunks and the strong fibrous mass d from the crura and aortic sheath the name of "radix me terica" is given Prolongations from it stream into gastro hepatic omentum (see Fig 7) to the hilum of kidneys, to the mesentery of the small gut, and to the of the œsophagus It is the centre round which respiratory movements of the abdominal organs take The radix mesenterica is not a human peculiarity, essential for the welfare of all animals that the blood, n and lymph systems of the abdominal viscera should b safeguarded. With the exception of the two parts mentioned, all the abdominal viscera are fixed to muscular walls of the abdomen and are subject to respiratory movements.

FIG 7



Vertical section of the abdomen of a child at birth to show the fixation of the abdominal viscera at the radix mesenterica

Fixation of the liver —The liver is fixed solely to diaphragm, but so strong and close is the bond between that its removal from the abdominal cavity is a difficulty Of the various structures which retain the liver closely pressed within the concavity of the diaphragm—peritoneal reflections, connective tissue adhesions, vascular bonds, and muscles of the wall of the abdomen—the last named are by far the most important. The visceral shelf on which the under surface of the liver rests, composed of the stomach, duodenum pancreas, colon, and right kidney, is maintained by the action of the abdominal muscles. The vena cava and hepatic veins, by their intimate fusion with the central tendon of the diaphragm on the one hand and the substance of the liver on the other, constitute a highly important bond. When one comes to deal with the other uniting structures of the liver, the connective tissue adhesions and peritoneal reflections, the ill-defined condition of their nature and nomenclature prevents an accurate description. I refer especially to the connective tissue which binds so firmly the posterior aspect of the right lobe of the liver to the arcuate fibres and right leaflet of the diaphragm and to the reflexion of peritoneum which surrounds the connective tissue bond (Fig 8). It represents the dorsal mesentery

---

[5] Die Entwickelung der Athemmechanik im Kindesalter Anatomischer Anzeiger Band xxii, 1902 p 119

FIG 8.

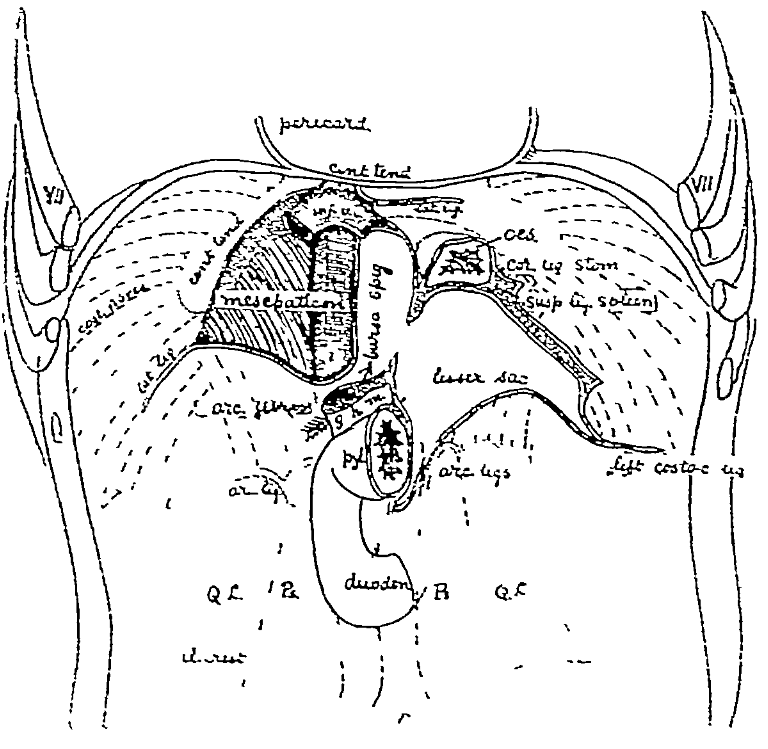


Diagram of the posterior wall of the abdomen, showing the attachments of the liver stomach, and spleen to the diaphragm. The arrow is placed in the foramen of Winslow

of the liver and therefore ought to be named the "mesepaticon."[*] It forms by far the chief passive bond of the liver The terms 'right lateral ligament" and left ateral ligament' should be reserved for the well marked membranous folds which stretch out to the right and left from the mesepaticon while the useless term 'coronary gament should be discarded. The suspensory ligament, he ventral segment, represents the ventral mesentery of the ver It is long and loose to permit the respiratory movements of that organ.

Bursa Spigelii or vestibule of the Lesser sac.—The diver culum of the lesser sac which separates the right crus of he diaphragm from the Spigelian lobe of the liver (see Fig 7) has scarcely received the attention it deserves. In his diverticulum or bursa the Spigelian lobe of the liver escends and ascends with each respiratory contraction of he crus. A better view of the bursa Spigelii is obtained hen the liver is removed (see Fig 8) when it is seen to be really the vestibule of the lesser sac. Although usually described as part of the lesser sac it is quite different in function and in development and more ancient in origin than the real sac of the omentum which lies behind the stomach and within the great omentum and opens into the bursa Spigelii in front of the cœliac axis. In all air breathing vertebrates the bursa Spigelii is developed as a diverticulum of the peritoneal cavity and growing into the dorsal mesentery separates the attachments of the liver from that of the stomach It is developed to allow the liver to accommodate itself to the filling and emptying of the lungs.

Respiratory movements of the liver.—If one accepts the conventional description of the diaphragm as a pair of ascending and descending muscular domes, then the viscera within each dome, the liver, the stomach, and the spleen must descend as visceral hammers amongst the viscera below them with each inspiration. Such a view holds true only for subjects in whom the thorax has been disturbed by disease or clothing and the normal action of the diaphragmatic fasciculi upset. To understand the normal respiratory movements of the liver it is necessary to remember (1) that in inspiration the bases of the lungs descend forwards, downwards, and inwards in the direction of the radix mesenterica and (2) that the liver lying in the floor of the right pleural cavity, has to be moved in the same direction to allow the expansion of the right lung to take place. The extent of the downward movement depends on the resistance of the belly wall muscles, in a marked thoracic type of respiration there may be no descent, but taking a type in which the thoracic and abdominal types are nearly equally blended the respiratory movements of the liver resolve themselves into the three rotations shown in Figs. 9 10, and 11.

The three movements.—1. The rotatory movement round a median antero-posterior axis shown in Fig 9 is well known. The lateral parts of the diaphragm being more muscular and more moveable than the central part the portion of the liver within the right dome descends downwards and inwards while the part beneath the central tendon remains nearly stationary as far as a movement in a vertical plane is concerned. (See Fig 10) 2. The rotation shown in Fig 10 is round a vertical median axis and is by far the most important of the three movements The long loose, suspensory ligament freely allows this movement. The forward swing of the right lobe of the liver in the third movement is produced by two sets of fibres (1) the costal fibres from the eighth ninth tenth, and eleventh ribs which, sweeping round the liver, are finally bound to it by the mesepaticon, and (2) the external intercostals by raising the abdominal ends of the lower six ribs upwards, outwards and forwards, assist the costal fibres in producing a forward movement of the liver 3. The third movement, represented in Fig 11, takes place round a horizontal axis drawn from side to side of the body While the posterior or dorsal part of the liver under the traction of the right arcuate and crural fibres, passes downwards and inwards and the Spigelian lobe slides down on the right crus and forwards on the pancreatic shelf, the anterior or subcostal part of the liver ascends with the sternum and ribs. The rotation of the liver occurs simultaneously with the tilt and swing of the cardiac platform described in my first lecture.

The respiratory movements of the liver are of more than theoretical import they explain the manner in which the organ is suspended and fixed, they take place without disturbing the function of the viscus, indeed their occurrence is probably a necessary condition of healthy hepatic action. Unfortunately the normal movements are liable to be disturbed from many causes. Relaxation or weakening of the wall of the belly may withdraw support from the visceral of descent, a part of the fundus is drawn within the dorsal mesentery of the thorax. Such cases have been recorded by Dr Rigby and myself[7], others have been described as diverticula of the œsophagus. Dr Andrews has also observed this displacement in cases of enteroptosis

---

[*] I use the term on the authority of Slade and White.

Diverticula of the duodenum.—Up to the end of the second month of development the duodenal loop, as is the case in the lower forms of primates throughout life, is freely suspended by a mesentery which is attached to the spine at the radix mesenterica. The head of the pancreas lies within its mesentery, the gastro hepatic omentum, which fixes the right aspect of the duodenal mesentery to the liver, contains the common bile-duct and part of the head of the pancreas After the second month of development the right aspect of the duodenum, with its mesentery, the head of the pancreas, and the lower part of the gastro-hepatic omentum, become gradually bound to the vena cava and hilum of the right kidney by loose connective tissue. The bond is never a firm one With each respiratory movement of the liver the duodenum and head of the pancreas yield to the hepatic pressure unless held in position by a well established resistance of the abdominal wall. In ptosis of the liver the head of the pancreas may lie just above the brim of the pelvis and in such cases a well marked diverticulum will be found in the inner wall of the duodenum just above the entrance of the common bile-duct (see Fig 13) The bile-duct is stoutly coated and inelastic, its upper end is fixed by the gastro-hepatic omentum to the diaphragm, its lower end perforates very obliquely the weak, yielding inner wall of the duodenum When the pressure of the falling liver causes the duodenum and pancreas to descend, thus throwing a strain on the common bile-duct, the weakest part yields and that is the area of the inner wall of the duodenum to which the duct is bound. The inner wall of the duodenum is thus pulled upwards into a tent shaped diverticulum of the kind to which Dr H D Rolleston has called attention

ON

THE CONDITIONS WHICH MODIFY THE CHARACTERS OF INFLAMMATIONS OF THE SKIN, AND THEIR INFLUENCE ON TREATMENT

Delivered before the Medical Society of London

BY H RADCLIFFE CROCKER, M D,
F R C P LOND,

PHYSICIAN TO THE SKIN DEPARTMENT UNIVERSITY COLLEGE HOSPITAL.

LECTURE II[1]

Delivered on March 2nd

MR PRESIDENT AND FELLOWS,—In my previous lecture I discussed the modifying influences of different local conditions, chiefly microbic either singly or in combination on the production of inflammations of the skin and this, for the sake of clearness, was done from the local standpoint only quite irrespectively of the individual in whom these processes were going on

But it is not enough for the microbe to meet the man, the result depends quite as much on the kind of man as on the kind of microbe It is a familiar fact that for the microbe to flourish or even to get such a hold as will enable it to breed at all, there must be favourable conditions of the soil which we can sometimes recognise while in other cases they escape us Thus persons who are exposed to the exanthemata frequently escape the disease at one time, even when the exposure has been frequent or prolonged while at another very slight exposure may determine a severe attack. For example, a lady nursed her daughter through scarlet fever in October and went away with her to the seaside during convalescence. On her return in December the mother put on a dress which she had worn whilst nursing the girl in the early stage of the disease and contracted scarlet fever in a typical, but not severe, form Here there was no lowered vitality to make her vulnerable and we can only state the fact without explanation that she was susceptible at one time and not at the other Very similar coincidences occur in the microbic skin diseases that we have been discussing, but at the same time there are some factors traceable in the individual which are worthy of attention. Even in such a simple matter as age there are often striking differences, thus, the microbes staphylococcus aureus and streptococcus pyogenes, which may be considered together for clinical purposes, easily infect children and suppurations therefore are often induced in them, which may be very free and tend to get deep and to infect the general system if not checked in an early stage. In a newly born infant, if the surface layers only are invaded, the lesion is generally a bulla, while in older children impetigo contagiosa occurs in vesicular or pustular lesions, adults either resist the infection altogether or the eruption is often only an excoriation in appearance and I cannot recall in the whole of my experience a typical impetigo contagiosa in a very old person. Ecthymatous sores may, however, occur in severely itching diseases such as pediculosis corporis, but even then they are seldom abundant though sometimes deep and severe As regards boils and carbuncles old people cannot claim exemption, and carbuncles are more likely to spread in them to a dangerous extent. When suppuration does occur in old people, the step from suppuration to gangrene may be a short one, fortunately, therefore most of the forms of suppurative dermatitis in the list given in my first lecture are uncommon with them Gangrene without previous suppuration is also apt to occur in the elderly, of this herpes zoster, especially of the ophthalmic division of the fifth nerve, affords frequent examples

At the other end of the chain infants and children under three years of age are particularly liable to multiple patches of gangrene which may supervene upon any pustular eruption of which the most common is varicella, but I have also seen it develop on an apparently harmless miliaria. This liability appears to cease after the child is three years old It is not known for certain what bacillus produces this form of gangrene, but the bacillus pyocyaneus appears to be the most probable one. Local bactericide injections check its extension and should be employed at an early stage or life will be endangered Of the other deeper lesions, boils occur at any age but carbuncles are rare in the young, fairly common in middle age, and more common still in old age. As is well known boils and carbuncles frequently occur where other depressing influences are present, such as diabetes mellitus or sewer gas poisoning, while in perhaps the majority there is no special departure from health unless from their size or number their own toxins excite septic febrile disturbance. Glycosuria is also a strongly predisposing influence to gangrene, both of small superficial areas and of whole limbs. Once successfully implanted the evolution of boils is not stopped when the malign toxic influences are removed though it is not infrequent to find them in abeyance even for months and then to recommence with another succession. The only explanation which I can offer of this is the latency of germs—a frequent phenomenon in microbic diseases and a source of perplexity and disappointment to both medical attendant and patient, too often it makes the latter unjustly dissatisfied with his medical adviser Some of the recrudescences are probably due to the revivifying influence of toxin absorption from the intestine or other viscera, but not all of them, and it is often not possible to do more than to make a probable guess. At the same time we should not accept too readily these theoretical explanations and should investigate carefully all the bearings of the case. Quite recently I saw a patient who had boils in the winter but not in the summer On investigation I found that he took much more exercise and lived out of town in the summer while in winter he had to keep very closely to his profession. Further inquiry showed that there was a strong probability of sewer gas poisoning in his private house which he occupied very little in the summer, and the real factor therefore was the change of residence

Seborrhœic inflammations are less frequent in advanced life and cease altogether in old people. Old age, on the other hand is a strong predisposing condition for eczema especially in its drier forms. What appears at first to be a very trivial inflammation often spreads very rapidly over a senile skin. This is partly due to the degeneration of the senile skin with its dryness, its feeble innervation, and its defective nutrition generally, and I am strongly disposed to think that secondary microbic invasion plays an important part in these cases, though its most striking feature of extreme pruritus out of proportion to the apparent amount of dermatitis is due to the degenerated innervation. Still more important than the senile skin is the senile condition of the viscera with the consequent deficient kidney and liver action and faulty elimination of waste products as well as the imperfect assimilation of food. It is these factors which are, in my opinion, chiefly responsible for the meagre success with which we often have to be content in very old people. Nevertheless we need not fold our hands over our patient, for treatment often meets with an unexpectedly good effect when we scarcely anticipate it. The indication is to wash out the kidneys and alimentary canal with weak alkaline waters, such as Contrexéville or simple hot water, preferably distilled, to keep the lower bowel empty, and, in short, to get as much out of the worn-out organs as medical resources permit.

---

[7] Proceedings of the Anatomical Society of Great Britain and Ireland, November 1901

[1] Lecture I was delivered on Feb 16th and was published in THE LANCET of Feb 21st 1903 p 491 and Lecture III will be delivered on March 16th

There are other tissue proclivities, both congenital and acquired. The congenitally dry skin is one of these. When the patient has pronounced ichthyosis it is readily enough recognised but when it is so slight as to be little more than dryness and perhaps slight roughness in parts it is easily overlooked, as the patient having always had it regards it as a normal condition and never thinks of calling attention to it. The clue to these mild forms is that the eczema of which he complains is always worse in the cold weather. The first touch of frost often excites it and the skin has a special tendency to chap and to crack, there is pityriasis of the scalp and the hair is thin, dry, and lustreless and the other evidences of a dry skin are readily found if looked for. It suggests a treatment in which the local applications should be of an oily or greasy character, or at least if lotions are applied they should contain a liberal proportion of glycerine. The administration of thyroid extract is sometimes advantageous, for though not producing a definite cure of the ichthyotic condition, it ameliorates it for the time being, and thus materially facilitates the cure of the eczema. The opposite condition of hyperidrosis is also a predisposing condition to certain forms of dermatitis. On the palms and soles it is a frequent factor of a form of eczema which leads to great hypertrophy of the horny layers and then, of course, the hyperidrosis ceases. Several papular and papulo-vesicular eruptions may also be excited when an excessive perspiration is checked by cold, such as miliaria of infants and adults and a papulo-squamous eruption generally considered to be a form of eczema[2] but really quite distinct. Acute miliary lichen planus may also supervene under similar conditions.

Another congenital condition though less easily demonstrable, is a liability to eczema on small provocation, either from without or within, possessed by many patients. Although eczema is not actually hereditary it is highly probable that a similarity of skin which will render the patient vulnerable is transmitted. The old French writers expressed this by saying that the patient had a dartrous diathesis but as that term assumed a great deal while it explained nothing it has justly fallen into disuse. At the same time, like many another old theory, it expressed a certain amount of truth which it behoves us to recognise. In practice all we can do is to use such prophylactic measures as lie in our power in the direction of the removal of sources of irritation either external or internal, and in young people to advise the parents as to their future career the life of a sailor for instance, being distinctly contra-indicated. When the disease is actually present the treatment would not be modified by our knowledge of this hereditary predisposition, but of course it would affect our prognosis of a definite cure. In psoriasis the hereditary element is more pronounced and if one parent is liable to psoriasis should there be several children one at least is almost sure to get it, but it is rare for the majority to have it, though in one family in my experience out of seven members two sisters and three brothers were victims of the disease. I should define the heredity as a tissue proclivity to grow the special microbe which in my opinion produces the eruption.

What we have to call "idiosyncrasy" whether congenital or acquired, exercises an important influence on the character of the eruption and its mode of evolution and in recurring eruptions, the constant character of this influence is very striking. Thus, erythema multiforme, which, as its name signifies, exhibits great diversity in the clinical features of the eruption in different persons, in its recurrences in any one individual shows remarkable constancy. If the first attack be nodular, papular or circinate, or whatever shape it may take, subsequent attacks will have the same characteristics. The case of a man with an unusual form of erythema iris illustrates this well. The disease is much less frequently seen on the palms than on the backs of the hands and the bullous forms are rare, yet in this man, in three successive annual attacks the disease always began on the palms and always took a bullous form.[3] The same fact is illustrated in the plate of psoriasis, in this disease the face and the palms are comparatively rarely attacked, but in one patient the face and in the other the palms and soles were invariably the parts first invaded. Again, a psoriatic or eczematous patient in whom pityriasis rubra has once supervened is extremely likely to have this rather rare *disease recur whenever the original eruption attacks him* afresh and here the knowledge of this can be turned to practical account by at once vigorously treating the primary affection and thus averting a very dangerous complication.

TOXIN ABSORPTION

A very powerful factor, in my opinion, in the production of eruptions is the formation in the viscera and absorption from them of toxins most frequently of intestinal origin. It is true that we can rarely in any particular case produce conclusive evidence that this absorption has caused the disease, but from time to time cases arise in which the probability is very strong that such is the case and there is an accumulation of facts which point in this direction. Granting that intestinal toxins produce eruptions, what forms do they take? The most frequent are varieties of erythema (morbilliform, scarlatiniform, or patchy), urticaria, eczema, and some forms of pemphigus. Here is an example. A boy, 10 years of age, was taken ill with febrile symptoms, some suffusion of the eyes, and a little coryza followed by a copious eruption of urticarial wheals in corymbose clusters scattered over the *trunk and to a less extent on the limbs, on the next day* this disappeared and an erythematous eruption of distinctly morbilliform character came out all over the body and the question of measles arose. I decided against this from the mode of development and from the absence of corroborative evidence (Koplik's spots were then not known), and the bowels being confined salines and enemata were given and large and offensive scybala were evacuated. The rash rapidly subsided and the boy quickly returned to health. Other children in the house remained well. The following case of dermatitis herpetiformis was probably of similar origin. A patient, aged 78 years, in good health for his age, had an attack of gastric disturbance with diarrhœa, of which he did not know the cause. A few days later he began to have groups of flat erythematous papules on the forearms and abdomen, on which vesicles and bullæ developed a few days later and a typical dermatitis herpetiformis was produced. The almost daily evolution of fresh eruptive elements led to exhaustion and death in seven weeks from the onset.

Sudden chills often appear to be, and I believe are, the exciting cause of eruptions of various kinds, erythematous, urticarial eczematous, pityriasis rubra and others the variety depending more upon the patient than upon the cause. They have a widespread usually symmetrical distribution either from the onset or they soon acquire it. In some cases the patient is quite well before the chill, but more frequently there is a predisposing cause already present. Here is an instance. A lady 26 years of age, seven months pregnant, rode outside an omnibus. The same night she had shiverings followed the next day by a scarlatiniform erythematous eruption on the upper part of the chest, the back of the wrists, the trunk, and the inner side of the thighs. It spread up to the face and down to the legs and was most marked at the knees, and in 48 hours from the onset it was universal. The temperature was at first 99·4° F., but it reached 101·4° with congested and swollen fauces and enlarged glands behind the sterno-mastoid. Scarlet fever was diagnosed by a physician to a fever hospital but she had not the strawberry tongue, she did not look ill, and she was quite lively, and I came to the conclusion that it was not scarlet fever—not from the morphology of the eruption which was typically scarlatinal, but from the mode of development and the fact of her general condition being good instead of her being profoundly ill, as she would have been in scarlet fever with that amount and intensity of eruption Further I had the advantage of knowing that she had had two previous attacks in connexion with pregnancy, in one of which I saw her just after her confinement, when the condition of the lochia left little doubt that the rash was of septic origin , also the distribution and development were the same as in the third attack. Her rapid recovery confirmed this opinion. In another case a policeman contracted a severe chill , this was followed by an erythematous eruption on the chest which developed into a universal pityriasis rubra. It had a prolonged course of several months but the patient finally recovered It is evident, therefore, that the same cause will produce totally different eruptions in different persons and further examples of yet other diseases in illustration might be given, but the above are sufficient for our purpose. For a time there was a tendency to scoff at chills as an exciting cause of eruption and many other diseases—pneumonia, for instance—because it was a bacterial disease, but although our predecessors had not the advantage which the knowledge of modern pathology gives they were very close observers of facts and these remain true though we give them a different explanation In my opinion, the most plausible explanation is that when the surface of the body is chilled there is a sudden and extensive contraction of the blood vessels of the skin, followed by wide dilatation, and during the latter there is a great withdrawal of blood often laden with toxin products from the intestine most frequently, but also from other viscera such as the post partum uterus, the liver in certain states, &c Many of these eruptions from chills being, therefore, really immediately due to toxin absorption the moral is to remove as far as possible the conditions which favour the production of toxins, such as constipation and all possible sources of septicism.

---

[2] Author's Atl there described as of seborrhœic origin
but further exper to its being a sweat eruption

[3] Plate III. Fig 1, of the author's Atlas shows one such attack of bullous erythema iris. Plate xxviii., Fig. 1, shows a psoriasis attacking the face in a diffuse form and Figs. 2 and 3 the primary involvement of the palm and sole.

In offering this explanation I do not wish to underrate the part played by the nervous system in such cases and, indeed, it is probable that in many diseases—urticaria, for example—the toxins act through the nervous system I can adduce an example of even more direct action An elderly lady, slightly gouty and distinctly asthmatic suffered from eczema which began in a slightly exuding patch on the right leg and was followed by the development of a good number of patches on the limbs and trunk consisting of roundish groups of papules and papulo vesicles which were somewhat rebellious to treatment but at last yielded and only the original patch remained owing to an unsuitable application having revived its activity Whilst in this condition she fell downstairs and was of course, much shaken , beyond a sprained ankle she was not otherwise injured, but within three days a large number of lesions of a totally different character appeared on the trunk and limbs, especially inflamed under the breasts and groins. This new eruption began as papules of the size of hemp seed with scaly apex which enlarged peripherally into scaly discs of the size of a shilling with a central adherent crust, but there was no discharge unless the crust was rudely removed Here, then, a nerve shock made a complete change in the eruption—though even in this case a toxin absorption from the intestine could be invoked with a fair show of probability , and in the following somewhat similar case intestinal disorder was actually produced by a fall. A carman was thrown from his seat to the ground, a distance of about 12 feet. He was, of course, much shaken but no definite lesion was produced , two days later he vomited repeatedly without apparent cause and was very constipated, which was not the case before the accident. Within a week of the fall he had an eczematous outbreak on the scrotum, penis, umbilicus, and forearms, quite symmetrical, in some parts exuding, in others dry , on the thighs there were patches of erythema of the size of the hand, well defined and not of the eczematous character of the rest of the eruption He got well rapidly with saline aperients and a calamine lotion

Such cases as these illustrate some of the great difficulties which we encounter in endeavouring to unravel the etiology of so many inflammatory eruptions The pathogeny of an eruption is not necessarily the same in different individuals and the problem is still more perplexing, even in the same individual, in successive attacks, while the eruption has the same mode of onset and character the circumstances which excited it may be quite different. Take such a disease as psoriasis, it is seen most frequently in early life , 72 per cent of the cases occur for the first time under 30 years of age, and the numbers below 12 years, between 12 and 20 and between 20 and 30 years, are practically equal—viz., about 24 per cent. At these ages the disease generally attacks apparently healthy persons and is most likely primarily microbic, at first from without and afterwards from within, and the general health is seldom a factor When the disease occurs for the first time between the ages of 30 and 50 years—and not more than 5 per cent. begin after that age—defective assimilation is frequently a determining cause and may lead up to gouty manifestations. A still more important factor is rheumatoid arthritis, by many considered to be of septic origin, and this disease strongly predisposes to psoriasis Thus, then, in the early cases the microbe was everything and produced the disease when the powers of resistance of the organism were presumably at their highest , while in the cases of late commencement either the microbe could not obtain entrance or it was powerless until the soil was modified by diseased conditions of the body itself You must bear in mind that in all the above cases I am referring exclusively to the primary attack. Recurrences may come on at any age and it is seldom possible to account for any one of them.

The Nervous System

The influence of the nervous system on diseases of the skin is important, but for the most part indirect, with the sole exception of herpes zoster Given any particular nerve lesion you can never say that you will certainly get a corresponding skin disease. In herpes zoster, as is well known, inflammation of the posterior ganglion through which the nerves pass which supply the skin area affected is nearly always present, but peripheral nerve irritation or inflammation of the trunk of a nerve may also produce it, but it is probable that even in these cases the ganglion is secondarily affected. Quite recently I saw a bricklayer, aged 70 years, who during cold weather had leaned with his left hand on some brickwork to steady himself while working with the other hand , the left hand became numbed from cold, and a day or two later a violent attack of herpes zoster appeared on the palm of that hand as well as on the back and extended up the forearm and half way up the arm, with gangrenous ulceration in some parts Herpes has also been found in connexion with diseases of the posterior columns of the cord and in the posterior nerve roots above the ganglion. In short, while no doubt inflammation of the posterior ganglion is by far the most common cause of zoster, it may arise from any part of the nerve chain from the posterior column of the cord to the nerve periphery

Apart from shingles although numerous cases of lesions of the nervous system associated with skin lesions are on record, yet the results are so diverse, even when the nerve lesion is apparently identical, that the nervous influence must be indirect and require some other exciting factor Moreover, in by far the majority of cases of lesions of the nervous system there is no skin eruption at all. Nevertheless there must be innervation present or no inflammation of the skin will be produced This is well illustrated in the following cases of small pox. In a case recorded by Bouilly and Matthieu intercurrent small pox occurred in a patient after section of the sciatic nerve and the non innervated limb remained free from eruption. On the other hand, Chevallier saw a case of small pox in a hemiplegic patient in whom the eruption was confluent and hæmorrhagic on the incompletely paralysed side and discrete and normal on the healthy side. In a hemiplegic observed by Jamin de St. Just scarlet fever supervened , for two days the eruption was limited to the healthy side and when it did attack the paralysed side it was pale and fugacious A few years ago my colleague, Mr Christopher Heath, excised the right elbow of a young man , when he was nearly convalescent he went home to visit some friends and shortly afterwards a vesicular eruption developed on the hand and forearm of the limb operated on followed in a day or two by a more generalised eruption, and when I was asked to see him I found that he had varicella and that the eruption was most abundant on the hand and forearm of the side operated on The explanation of these apparently contradictory cases is not so difficult as it appears at first sight. In the first case there was no innervation and therefore no eruption , in the case of scarlet fever, with slight and fugacious eruption, there was a little vaso-motor influence left, but no cerebral , in the hemiplegic with small pox cerebral influence was abolished while the sympathetic was for the most part undamaged and unrestrained and the eruption was therefore confluent, in hæmorrhagic small pox both cerebral and sympathetic influences are paralysed by the poison and there is no eruption but only extravasation from the walls of the non-innervated vessels giving way In the varicella case the *nervous supply was slightly damaged but not destroyed and* the eruption, instead of developing in the usual positions, came first at the place of the least resistance. The outcome of this, therefore, is that the cerebral influence is a controlling one over the vaso motor centres and that the functional preservation of the latter are essential factors in the production of inflammation of the skin.

In lesions of the spinal cord bullous and vesicular eruptions are the most frequent as a sequence of inflammatory lesions of the posterior column. Less often ulcers and gangrene and vaso-motor troubles of an erythematous or urticarial character supervene, but there is no certainty about it, and even in locomotor ataxy eruptions are much more frequently absent than present Bullous eruptions may arise where there is damaged innervation in two ways, either from inflammation of any part of the sensory nerve path from the centre to the periphery or from the non protection from injuries of the part in which the innervation has been cut off. This is well seen in leprosy, in the early stage of the nerve form, when there is inflammation of the nerve set up by the lepra bacilli, bullæ often form on the fingers and toes in the area of distribution of the neuritis associated with shooting pains. They are spontaneous, small, and numerous, and the surface is painful. In the late stage of the same disease, when the nerve is utterly destroyed by the pressure of lepra products on the nerve fibres, the bullæ are large and solitary and appear on the non innervated area after slight injury or exposure to cold or heat of which the patient is usually unconscious, as the part is anæsthetic. When the nerve interference is partial from an injury ulceration follows the bullæ and sometimes there is suppuration like a whitlow at the commencement.

When we consider the influence of the *nervous system* on *the distribution of eruptions* we find it rises to the highest importance. Examples of many inflammatory eruptions such as zoster, eczema, and lichen planus occur parallel to the axis of the limb with a more or less linear arrangement, but it is more frequent in some congenital affections such as ichthyosis hystrix, including the linear verrucose nævi, glossy skin, &c. In a case under the care of Brouardel a man, 60 years of age, had a contusion of the shoulder followed by shooting pains down the arm and in 40 hours an eczema developed limited to the radial nerve distribution and became rapidly confluent, but got well in a fortnight.

Of far greater practical importance is the influence of the nervous system in the distribution of eruptions in the vaso-motor areas. Such is that of the bust and arm distribution which is most clearly demonstrated in xerodermia pigmentosa in which it is very constant, rarely extending lower than the level of the upper portion of the sternum in front and of the nucha behind, on the upper limbs from the middle of the back of the arm behind, sloping downwards and forwards almost to the flexure of the elbow in front while it covers the whole forearm and the back of the hand. This distribution is often seen in acute eczemas of the upper part of the body and for some time may be confined within these limits, though it will sooner or later spread beyond them if it is not efficiently treated. The recognition of this arrangement may often be turned to practical account in cases, not infrequent, in which the inflammation recurs again and again without apparent cause. The centre for this distribution can be got at through the cervical enlargement and I have found that counter-irritation over it—preferably by a piece of mustard leaf though other counter irritants will do—has a marked controlling influence, if applied early in sometimes preventing, and generally diminishing, the intensity of the recurrence of the accompanying pruritus. The latter symptom, which often rises to its highest intensity, and is quite maddening sometimes in eczema of the scrotum and neighbourhood, is often conspicuously relieved by similar counter-irritation over the lumbar enlargement which has a similar controlling influence over *inflammations of the lower* extremities as the cervical enlargement has over those of the upper In using this method of treatment the best results are obtained when it is used just before or at the very commencement of a recurrence. It should not be used in the declining stage. A smaller area but one affected by several diseases is the centre of each cheek, it is frequently the first affected in lupus erythematosus together, sooner or later, with the bridge of the nose, in acne rosacea, together with the centre of the face—viz., the forehead, nose, and chin, in a few cases eczema also is limited to this region, it can be influenced by counter-irritation over the mastoid on each side

PREGNANCY

Pregnancy is responsible for a few eruptions, but the principal and most distinctive one is the so-called "herpes gestationis" which is now acknowledged to be a dermatitis herpetiformis with a special etiology as precisely similar eruptions may occur both in single women and in males. Its general behaviour in relation to pregnancy is interesting *Once it has occurred in relation to this state it is almost sure* to recur in every succeeding pregnancy One of my patients had seven pregnancies in 11 years and it attacked her at each gestation. It tends to begin earlier and earlier in the pregnancy, until sometimes it is the first intimation to the patient of her condition With exacerbations and remissions it then continues throughout pregnancy and shortly after parturition an attack of explosive violence occurs and then the attacks diminish in severity until they cease altogether in from three to six weeks. Of course, they do not all run this regular course, some begin in the same month of each pregnancy and may stop before parturition and may recur after it, and some begin just after pregnancy They may also last for a very long time after parturition or may even become chronic or recur without a fresh pregnancy In one of my cases at the fourth attack the patient was found not to be pregnant but to have cancer of the cervix uteri. The same kind of eruption has even been known to begin independently of pregnancy, to disappear when this occurred *and to recur when the* menses appeared again, but of course this could not be called a herpes gestationis

THE INFLUENCE OF SEASONS.

The influence of seasons on eruptions has long been recognised in certain forms of disease, such as erythema multiforme and psoriasis. Both of these diseases show a decided tendency to recur in the spring, but unfortunately they do not restrict their activity to this season and many patients show special idiosyncrasy as to the *time for recurrence.* Thus in some, the onset of cold weather often excites an outbreak, but whatever the period of eruption may be that time is adhered to for the most part in future attacks The urticaria of infants also often dies down in the winter *and revives in the* summer and true prurigo also has a similar tendency though in some cases in this disease the season is reversed Many other examples *might* be given, but there is a more interesting class which belongs especially to summer or winter, though in certain circumstances minor attacks may be produced in what may be called their off season

Hutchinson was the first to call attention to one variety of these cases and Bazin to another These two varieties are pretty definite in their characters while in many members of the group the characters of the eruption are not so defined and their diagnosis rests rather on their general behaviour than on their morphology Hutchinson called his first cases "summer prurigo and there is a type which this *title fits fairly well.* It is distinguished by commencing in childhood, seldom before eight years of age, and attacks the exposed parts—viz., the face, back *of the hands*, and wrists—the face being the part principally involved, and it is only in exceptional cases that these limits are exceeded. The primary lesion is a simple one, a flatly convex erythematous papule which soon acquires a central scab from scratching or rubbing for the pruritus is most intense at the onset and height of the attack However abundant the eruption, the lesions nearly always remain discrete and this is an important diagnostic point. Unless there are secondary pus inoculation sores, the eruption is particularly dry and rough and suggests the use of ointments, but these in my experience invariably increase the irritation and the *patients* tell you *flatly that* they cannot use them Astringent drying lotions especially the organic silver salts, give the most relief and enable the patient in a *great measure* to abstain from scratching and then improvement occurs unless a fresh outbreak is produced by a direct exposure to the sun or to a bitterly cold wind. A precisely similar eruption may occur in winter in some patients, in these cases the cold winds being the greatest provocative and the sun's rays having less irritant action. The winter cases are much less common than the summer ones, but both the summer and winter cases continue to be liable to recurrences according to their special peculiarities year after year or several times a year until the patients reach adult age when the liability gradually ceases and it seldom persists after the age of 25 years The skin from the repeated inflammation is left rather thickened, pallid, and sometimes superficially scarred from the repeated excoriations.

Other forms of this summer eruption are papulo-erythematous, papulo-vesicular, and vesiculo-pustular, but the most common form consists of pale red conical papules with or without a little clear fluid at the apex, which dries up and shells off, leaving minute shallow scars which in the course of time impart a mottled look to the whole face The distribution, though always predominating on the exposed parts, is less limited than the summer prurigo type This does not exhaust the varieties in form of these eruptions, but the general behaviour being the same in all enables them to be recognised in spite of their different morphology

The summer disease first described by Bazin is known by the name of hydroa vacciniformis seu æstivalis It is fortunately rare, as it produces great and permanent disfigurement and even mutilation of the face and ears, so that in the final cicatricial stage the patient looks as if he had had a severe lupus, as the nostrils and ears are partially destroyed, there may also be extensive scarring of other parts of the face This disease generally begins in the first three years of life, and nearly all its subjects have their worst attacks almost exclusively in the summer from the direct effect of the sun, but artificial heat and cold winds will sometimes excite it, the eruption breaking out a few hours after exposure and recurring whenever the patient is subjected to the excitant from spring to autumn while he is comparatively free from October to February The attacks become milder at puberty and generally cease by the time that the patient has grown up The majority of patients are boys, but girls sometimes suffer from this complaint. The lesions which characterise this disease are vesicles of the size of hemp-seed on a red base which umbilicate and become pustular like small pox or spread peripherally like a vaccine pustule and finally dry into a crust which falls off in time and leaves a pitted scar This was the type that Bazin described as hydroa vacciniformis, but these vesicles may crowd together and coalesce into flattish bullæ with a red areola, the fluid portion drying up from the centre to the periphery and forming a superficial or thick scab, in the latter case producing a deep scar, the whole process lasting two or three weeks. The chief seats of the disease are the face, ears, neck, and hands, but the unexposed parts of the limbs may be affected while the trunk is rarely involved.

Unfortunately, as all these recurring eruptions are excited by atmospheric agents, drugs, either internally or externally, have only a palliative influence on each attack of the eruption All our efforts must therefore be directed to induce the patient not to expose himself to the sun and wind more than can possibly be helped The whole class are angio neuroses with a congenital vulnerability of the skin something like that of epidermolysis bullosa, but that requires slight injury such as blows or friction to bring up the bulla

INGESTA.

With the exception of certain drugs and alcohol few ingesta affect inflammatory eruptions directly Alcohol dilates the cutaneous capillaries and so increases the congestion and in alcoholics who are also the subjects of psoriasis the disease is often recognisably modified, large livid red patches are produced in which the scales form too rapidly to remain adherent into crusts, though blood stained inflammatory crusts are sometimes produced by scratching and with the other characters make a distinctive picture indicative of the patient's habits All forms of dermatitis, especially as regards itching, are no doubt aggravated by anything more than a very moderate use of alcohol in its simplest forms and some patients cannot take it at all, but there is nothing in the aspect of the skin disease alone which shows that the patient exceeds his limit whatever that may happen to be. The effect of wines, beyond what is due to the quantity of alcohol they may contain, is only indirect. In many patients, especially those with a gouty tendency, disorders of the liver and alimentary canal are produced within a few days of taking them with a constancy which leaves no doubt of their being in the relation of cause and effect and they may then produce an aggravation of any eruption to which the patient may be subject.

DRUG ERUPTIONS.

The subject of drug eruptions is too large to enter into in any detail. Although there are a large number of medicaments which are capable of exciting eruptions under certain conditions or in certain persons yet in practice untoward results of this kind are rather rare With the exception of those produced by bromides or iodides none of these eruptions are distinctive enough to indicate the drug which has produced them, and it is only by the knowledge that the patient has had a particular drug followed by a rash that the cause and effect can be connected. Of these non-distinctive eruptions, various forms of erythema, scarlatiniform, morbilliform, or patchy, are the most frequent, but urticaria and purpura are fairly common and next come vesicular, bullous, and pustular rashes. On all these I need not dwell, the mere enumeration of the drugs which may possibly produce them is too like a catalogue to be interesting or instructive.

With regard to the bromide and iodide eruptions the matter is on a different footing Although sometimes like each other the agminated forms are quite distinct from all other forms of eruption and a positive diagnosis can generally be made not only when there is no history of these drugs, but even when the history appears to negative such a supposition. Certain general statements may be made as to the circumstances under which they are liable to occur It is seldom a question of dose, small doses frequently produce an eruption while large ones may be taken with impunity I know of a lady who took, not by my advice, 80 grains of iodide of potassium three times a day for nearly a year without apparent injury, while the eruption shown in the plate[3] came out after a few five-grain doses. Nevertheless when the system is saturated with the drug, as happens sometimes with bromides with chronic epileptics, a violent eruption sometimes occurs without any warning, especially if there is any check to its rapid elimination. This last is the true cause of nearly all cases in adults, and if a pronounced bromide or iodide eruption occurs after moderate doses of either of these drugs the urine should be tested and the heart examined, for it, or the kidney, or both, are almost certainly at fault. In the case just alluded to, with what looks like a bullous iodide eruption the patient had pronounced albuminuria from the smooth white kidney, so also had the man illustrated by this photograph in whom the diagnosis was made in spite of a denial that iodide had been given—the source of fallacy being that the man had taken a quack blood purifier well known to contain iodide of potassium In another case where I was asked for a diagnosis the patient had been sent into a small pox hospital and advanced mitral disease was present and was the determining factor of the eruption A similar case has been recently recorded in one of the medical journals. Infants are especially liable to the eruptions from quite small doses which are comparatively common since bromides have taken the place of the gum lancet, but even before the teething period it may occur through the maternal milk when the mother is taking the drug A point which throws one off the scent sometimes is the fact that the outbreak often occurs a week or two after the drug has been stopped, the explanation being that both bromides and iodides are diuretics, and when this action ceases soon after the drug has been stopped there may be still enough circulating in the cutaneous vessels to set up inflammation. Another misleading fact is that these drugs have a special predilection for scar tissue, and I have seen several cases in which the vaccination scars have been the first point of attack and have led to the idea that the vaccination was at fault.

I will not go into detailed descriptions of these eruptions —they are to be found in all the text books—but I will only emphasise the fact that the most distinctive character of the bromide pustular eruption is the agmination of small pustules on a raised red plateau derived almost entirely from the swelling and proliferation of the prickle-cell layer and it therefore leaves no scar when it disappears unless a deep suppuration has been excited secondarily Such a lesion is absolutely distinctive.

The pseudo-bullous iodide eruption is also distinctive, it consists of transparent raised lesions like distended but flattened bullæ crowded together in irregular areas, when the supposed bulla is pricked, however, only a small drop of fluid escapes, for the lesion is really a solid œdematous swelling of the rete cells. Besides these characteristic bromide and iodide lesions there are several less distinctive eruptions produced by these drugs—erythema, in some cases like erythema nodosum, urticaria, purpura, of which some cases have been fatal, isolated pustules, true vesicular and bullous eruptions, which are rare, gangrene, and, in the case of iodides, anthracoid and vegetating lesions—the latter are very rare

---

[3] Plate xxxvi. author's Atlas

Iodide of potassium should not be given to persons suffering from acne rosacea, which is often much aggravated by it, or in cases of bullous eruptions such as pemphigus and dermatitis herpetiformis, as it often greatly increases the severity of the lesions, and I have seen the bullæ become hæmorrhagic and even gangrenous as a consequence.

GOUT

Perhaps you are surprised that I have not given gout a primary position as an etiological modifying factor of dermatitis. I have purposely not done so for several reasons. While I do not doubt that gouty patients are easily predisposed to, or easily get, eczema and to a less extent some other forms of dermatitis, such as some forms of psoriasis which commence in middle life, some cases of pityriasis rubra, and some of the erythemata, there is no doubt that its influence has been overrated in the past by the profession, so much so that the public, who are usually a generation behind us, regard eczema and gout as almost synonymous terms and I am not infrequently asked by anxious mothers of eczematous infants in arms whether I think they have gout in their systems. The fact is, a gouty person is one who is vulnerable to inflammations of any or all of his tissues, especially of his mucous and synovial membranes and his skin, but it is not possible to decide solely from the kind of dermatitis present whether the patient is gouty or not, and it is sound practice only to infer it when there is other evidence in himself or in his family history No doubt if there is such evidence it is wise and right to treat such a patient by diet and medicines calculated to combat his gouty tendency, but we must all confess how often we fail to get a satisfactory result as far as the skin is concerned after we have done our best to fulfil the supposed indications.

Much more frequently we find in eczematous patients in middle life and beyond it, that a condition of faulty assimilation of food exists from imperfect liver action, dyspepsia of various kinds, constipation in women and its train of evil consequences, and when there is constipation you do not know where you are until you have got rid of it, at all events for a time. These conditions, too lead up to gout if allowed to go on unchecked and we must endeavour to modify the patient's mode of living as regards eating, drinking, and exercise. These are, however, to practitioners like yourselves familiar truisms and I will not dwell on them further but only ask you not to be eager to see gout in every case of eczema unless the general evidence is decidedly corroborative and even then the real factor is often the disordered condition of the alimentary canal which is so commonly associated with the gouty state, and probably many symptoms which we ascribe to uric acid are often really due to the absorption of toxins or ptomaines from the catarrhal condition of the intestinal canal. Intestinal disinfectants, therefore, such as salol are indicated, together with such a dietary as will not excite fresh catarrh and fermentation in the food.

While I have not yet exhausted the subject of etiology as it influences the form and course of inflammations of the skin—the subject of vaccination among others being untouched—I have come to the end of my time and I fear of your patience and will therefore pass on to the discussion of treatment in my next lecture.

ROYAL INSTITUTION —The Friday evening discourse at the Royal Institution on Feb 27th was delivered by Dr Adolf Liebmann the subject being Perfumes Natural and Artificial. Considerable reference was made to the success of chemical methods in the manufacture of essential oils identical with those upon which the fragrance of some plants depends the artificial products being in an extraordinary degree cheaper than some of the natural ones. Vanilline for instance, an odorous crystalline substance contained in the vanilla bean, in 1876 was worth about £150 a pound, but at present the price is only about £1 10s

THE RISE OF BLOOD PRESSURE IN LATER LIFE[1]

BY T CLIFFORD ALLBUTT, M.A., M D, D Sc, F R.S, F R.C P,

REGIUS PROFESSOR OF PHYSIC UNIVERSITY OF CAMBRIDGE.

WHEN in the third quarter of the nineteenth century I entered the profession of medicine physicians were much occupied in the deadhouse, contemplating the ruins of mortality Surrounded by the last dilapidations of the human frame they laid bare almost daily in its inward parts some previously unknown wreck, blight, or decay In the wards, meanwhile, before Darwin's theory had changed the habit of thought, the mind of the physician was coloured by notions of the fixity of kinds, he was apt to attribute a certain fixity even to the species of disease, especially to those kinds which, as the phrase ran, were organic rather than functional. Functional diseases made no appearance in the deadhouse, indeed, many of the acute diseases had proved, in recent experience, to be, if often violent, yet temporary oscillations, tending, if let alone, to recovery the end of chronic visceral disease, however, seemed to be inevitable death in derision of drugs Thus it happened that to organic diseases, too rigidly conceived as entities, names derived not from original causation or clinical character but from the ultimate forms of destruction became attached, and as a student I well remember how one distinguished teacher and another would display a shrivelled kidney or liver, a distorted heart, or a softened brain, and ask disdainfully of what use medicines could be for such degradations, even in their earlier stages, how organs with such proclivities were to be converted by prescriptions? Not more than fifteen years ago I said to a late physician, one of the ablest of his generation, "I am sick of diseases, I want to know origins and processes" We were walking together and he, stopping, turned upon me and exclaimed, as if new light were breaking in, "Processes? Ah, processes! Yes, the pathology of processes is the work of the future." I had urged, for example that bloated or withered kidneys are not engendered of vice in the kidneys themselves but of the prolonged, uniform, symmetrical action upon both of them of some unknown poison or poisons circulating in the blood, an influence, furthermore, by no means confined to these organs but visible in widespread effect elsewhere in the body that to speak of such cases as cases of kidney disease is therefore misleading, and so on of other post-mortem wreckage. The discovery of such utter mischief after death is matter not for our despair but for our disgrace, it is not a declaration of the impotence of therapeutics but black evidence of our blindness and negligence in the past history of the individual If in the pathology of the dead there remains much to be discovered, we have nevertheless made great way in it, the pathology of the living is hardly begun.

These arguments may seem to savour of platitude, but I think even to-day that they have not lost their application, that you will not find it hard to carry your minds back so far as to realise the change—the transformation—which is passing over medicine at this time, and that you may find it still less difficult to accept at my hands some attempt to study disease at its sources rather than at the term when its work is done.

To my friendship with the late Dr Mahomed I owe much of my conviction of the clinical value of the study of arterial pressures, and a few years later I was encouraged and aided in this study by the late Professor Roy Thirty years ago physicians were putting the sphygmograph aside as "of no use in diagnosis," but, as I have said physicians were then too much ruled by the statical conceptions of the deadhouse They demanded of the sphygmograph that which it cannot directly indicate—namely the site, form, or even the very existence of particular local lesions in the heart. Yet Mahomed Sanderson, Galabin, and others—to speak only of English physicians—testified even then to its capacity of exhibiting, within limits, the dynamical conditions of the circulation, the kind and distribution of work done, which, after all, is the chief care of the physician And how imperfectly we had availed ourselves of this capacity of the instrument we may learn from the remarkable treatise on "The Pulse" published but a few months ago by Dr James Mackenzie. Unfortunately the sphygmograph, valuable as it is, when handled by those who are well aware of its limits, in the record of modes, forms, and distributions of pressure, cannot measure positive pressures. For many years, therefore, until lately when pressure gauges or sphygmometers of some trustworthiness were put into our hands,[2] I have had to compare arterial pressures as best I could with the practised and attentive finger and to go without units and records. Thus, unsupported by permanent numerical computations, I found it a difficult task to convince my brethren of the importance even of approximate estimates.

---

[1] A paper read before the Royal Medical and Chirurgical Society on Jan. 13th, 1903 The substance of this paper was contained in my Hunterian *Lecture for* 1895 and in one of my *Lane Lectures* in 1893.

Arterial pressures vary very widely. If I lift a chair from the ground my arterial pressure may rise 20 per cent and fall again as rapidly as I come to rest. During the use of the sphygmometer, if the patient be not cautioned against contracting his muscles—if, for instance, he be seated in a cramped position—the pressure may fluctuate considerably. On a certain occasion I observed a high pressure in a patient in whom a high rate was not anticipated. No fault was found in the parts or arrangements of the instrument, and a second inflation revealed a still exorbitant though a lower rate, a third but a few minutes later registered an ordinary rate of about 120 mm. Hg, and remained steady about this figure. The previous excess I should still have attributed to some experimental fallacy, had not the patient, as I put the instrument aside, said to me that he had feared from it a violent electric shock, such as one which many years before at a fair had put him in an agony which he had never forgotten. As the shock did not occur he was reassured, and the pressure fell. In patients who enter upon a consultation with acute anxiety of mind the pressure at first is often excessive. When close accuracy is of importance it is well then to take two observations, one as the patient undresses, another, after all other physical examination, before he puts on his coat. The large majority of my observations are taken upon the patient seated easily at my table, it is better to keep to a uniform method, and in private practice this position is more convenient than recumbency. Observations on patients in bed rule rather lower, but in my practice they have been comparatively few.

With Hill and Barnard's sphygmometer the pressures of adults vary from 95 to 105 mm. Hg in temperate young men much occupied with athletic exercises, to 250 mm Hg (the highest figure in the scale) in disease,—as, for example, in Bright's disease.[3] Between these extremes every degree of variation may be found. I often apply the instrument in cases of life insurance, and in healthy men in middle life it should not record more than 120 mm Hg. I have never applied it to a healthy woman nor to a child, but by the finger I have often noted high arterial pressure in children.

In sufferers from arterio sclerosis—I use the name arterio-sclerosis loosely for present convenience—exorbitant pressures are often but by no means constantly found. Between disease of the arterial tree and blood pressure there is no direct relation, in arterial disease, even in the extreme degree of it, normal or relatively low pressures are commonly observed but I often notice that in cases of arterial degeneration the reading extends uniformly over a wider range of the scale—say over 15 or 20 units, in which cases I record the mean figure and the extremes. In denying that elevation of blood pressure depends directly upon arterio-sclerosis I have stood alone for some years, against the high authority of von Basch and many others, but I think that some recent observers now admit the validity of my contradiction, and the matter is one of cardinal importance. So far as intermittent observations are to be trusted, I repeat that pressure may be, and often is, low throughout the course of arterial degeneration, or, again, having been high, it may fall, though of course, in some elderly persons with arterial decay occasional transient attacks of high pressure, such as occur at times in all of us, may be observed. I need not add that a considerable and persistent fall late in a case, a fall not a result of treatment and not coincident with general amelioration, usually signifies heart failure and presages death within a few months, for it is remarkable how long high pressures are maintained, even when the dilated and overwrought heart is labouring towards the end of its day. When the subject of arterio sclerosis begins to be short of breath he has entered upon the last stage of his pilgrimage.

If, then, arterial degeneration be a *vera causa* of elevation of blood pressure its effects may be and often are so modified by incidental and coöperative conditions as to be negligible. In many cases of arterio sclerosis in which the blood pressures are not high, to the best of our knowledge they had never been high. Conversely, however, high blood pressures cannot long continue without straining the vessels, and I suggest that in elderly persons, in whom taint of lead, of syphilis, of alcohol, or other alien infection is set aside, and kidney disease also excluded, arterio-sclerosis be divided into two kinds, one the result of persistent high blood pressure, the other the result of some more intimate causes, perhaps some unknown poison, or the tooth of time. It is very difficult in arterial diseases to find distinctive histological marks of kind, even in a kind so distinct as the syphilitic, the characters seem to depend more upon the rate than upon the kind of the change. But I think that what I am wont, speaking clinically of the radial and brachial, to call the "leathery" vessel is suggestive of prolonged high pressure, persistent or past. The leathery vessel occurs in two forms—as the narrow and wiry and the voluminous vessel, the former being the more difficult condition to cure. Fulness of an artery is, of course, no indication of high pressure. The quality of the arterial coats is more easily felt in the brachial artery, on semi-flexion of the elbow, but the volume of the brachial may be normal or excessive when the radial is contracted. A certain degree of sclerosis does not render an artery incapable of response to vaso motor influences.

The leathery artery sometimes becomes calcareous, or is associated with calcified vessels elsewhere, as, for example, in the brain, but when calcification is a prominent and comparatively early feature in the superficial arteries pressures are apt to be moderate or even low. In the so-called "ipecacuanha radial" high blood pressure is by no means the rule, and as high pressure is not the rule in these cases so apoplexy is not the common event of them. Old persons with very calcareous and often grotesquely tortuous arteries, but with low pressures, are to be found abundantly in every workhouse or asylum where work is nominal and diet spare. They live long and die of an atrophy. Thus softening of the brain and gradual or rapid arterial obstructions occur in the group, but cerebral hæmorrhage may be called rare in them. In the wealthier classes these patients are found rather among the women, who are less addicted to high living.

Under conditions of high arterial pressure, on the other hand, of whatsoever causation, apoplexy is frequent, apoplexy, uræmia, and outworn heart account for the end of most of these patients. Yet it has been a matter of surprise to me to see that very high pressure may be maintained, as it would seem, even for years, without much more apparent deterioration to the arterial tree than time of life might account for. I come here to-night, however, to urge an earlier recognition of such rising pressures, and the timely use of therapeutical means to prevent the strain and break up of the circulatory system. Herein, however, is an initial difficulty that the subject of high pressure may not soon feel ill, nay, a steady maintenance of high pressure in the brain may conduce for a while to a sense of vivacity and endurance. The heart has grown up to the work, and let me repeat my opinion, though now necessarily without argument, that the arteries hypertrophy likewise in the muscular coat, so that until these compensating growths in heart and artery dwindle or deteriorate, usually after the fibroid form, the patient may believe all to be well with him and may not seek the physician till considerable mischief is done. Not infrequently, however, such persons come before us in an early stage of rising pressure, by the chance of some intercurrent disorder, or on the prompting of some vague discomforts, such as fatigue and low spirits.

---

[2] My own observations have been taken with von Basch's instrument and Hill and Barnard's. I have obtained better results with the latter instrument. Dr Oliver's sphygmometer is well spoken of but as yet I have no experience of it; it has seemed to me better to keep to one and the same instrument. Von Basch's instrument or at any rate that one which I possess registers 20 mm Hg above Hill and Barnard's and thus I have been led occasionally to make false entries in my notes (e.g., Practitioner January 1902, p 7 "120 to 125" should read *95 to 100*.

[3] On the day when these words were written I found maximum pressures of from 230 to 250 mm. Hg in a man, aged 65 years whose arteries were yet fairly healthy and in whom were no symptoms of renal disease. He complained of slight vertiginous attacks, lassitude, melancholy, and some loss of flesh.

Let us take such a case, say, in a patient, 50 years of age, a professional man, perhaps a merchant or a student who lives a sedentary life but lives well—for mental work and business cares create a desire even for more and richer food than is excited by bodily exercise in the fresh air, though they do far less for excretion. His sleep becomes disturbed, sick headaches are more frequent, he is moody in rising from bed and is fretful and apprehensive until he warms to his day's work, a good luncheon and a glass or two of sherry improve matters, and in the evening he dines out cheerfully, denying himself nothing of meat or drink. We may tell him that his liver is out of order, we may change his wine to whisky and soda, we may exhibit mercurials and salines, and send him to one of the spas, or we may do worse, we may not dwell on the laboured quality of the pulse, we may listen to the cuckoo cry of overwork, his wife will implore us not to lower him, urging that he is always better for his wine, and that a tonic and some rest are all that are needful and too often he gets the tonic, and is sent off for six weeks holiday wherein to do as he pleases. In order to gain strength he indulges his appetite, but as he does not dine out, and gets plenty of air and exercise, he comes home better, yet only to repeat the same experiences nine months later and to prescribe a holiday for himself, perhaps without consulting his physician So things go on, until one day he has a hitch in his speech, a cloud of albumin is found in his scanty and lateritious urine, and a trace of œdema rises upon his shins his pulse is now tighter than ever, his arteries are stretched like an old glove, and his heart is big and clanging Partially remediable his state may still be, he may live for a year or two, but he is past cure. At one time I busied myself with deobstruents, rigid diet, and regulated exercise, to turn such a patient back into health, but even in earlier stages than this I was forced to realise that in the corporeal as in the moral sphere repentance may come too late. We may succeed more or less in our immediate purpose, the pulse does become softer under the finger perhaps much softer, the heart comes in a little, the apoplexy or the pulmonary congestion is staved off, but the patient pettishly persists that he is no better And he is right, the stroke of death may have been parried but what of that to a man who is good for nothing? Such a case, perhaps you will say, was a bad one, then I will dwell upon a man not so old, not yet incapable of some hard work, one whose deteriorated cardio-vascular state is apparent only to the skilled observer, but whose blood pressure for two or three years has been from 150 to 180 mm. Hg and whose vascular system has thereby become stretched and inelastic, even in him treatment now can be but a compromise. If you bring his blood pressure down to the normal you will make him slack and spiritless, his circulation has become adapted to an abnormal capacity and you have henceforth to steer him as you can between the listlessness and malaise due to a reduction of pressure below his acquired habit on the one hand and an apoplexy on the other This is a task of much nicety and vigilance, and it is as likely as not that meanwhile the patient, who cannot enter into your refinements, will desert you for some more thoroughgoing practitioner

But now let me suppose that the finger, educated by the discipline of the sphygmometer leads us to suspect an abnormally high blood pressure and that we by the machine verify this in the first stage of the perversion—that is, during the initial disorder of which I spoke. In this period no cases lend themselves more satisfactorily, not only to palliation, not only to temporary amendment, but even to permanent cure. If excessive pressure be recognised in its earliest phases the course is clear, the treatment is not difficult, cure is fairly certain, and with due watchfulness in years to come shipwreck may be wholly averted. I cannot, then, urge too strongly the perils of neglecting these incipient increases of blood pressure and the importance of educating the finger in the early detection of them. Unfortunately, in this incipient stage very few physicians are alert to detect this process, so baneful in its ascendancy but if withstood in its first manifestations, so fugitive, for, unless the case be one of Bright's disease, we are too apt to be indifferent to some excess of pressure and early cardiac hypertrophy is not easy to recognise. Nay I have often heard patient and physician congratulate each other that at any rate the pulse is a good strong one. I am ready to admit that high pressure in the radial is not always unmistakeable even to the vigilant touch, although the aortic clang may be altered and the heart's apex a trifle outward Often even then the pressure gauge is needed to convince us that the heart is thrusting against abnormal resistance. In the small hard pulse the hardness may escape notice in the small size of the vessel, especially if the wrist be fat, moreover, these contracted vessels do not so readily become tortuous, indeed, when the artery is larger and laxer and the coat thickened, it is often difficult to be sure of excessive pressure, even when recourse to the pressure gauge, which must always be used in case of doubt, may prove it to be far above the normal. The reason of this latency of excessive pressure to the touch is a little difficult to understand, fortunately, the fallacy is more common in later stages when other features have become obvious The sense of duration of the wave is often a more definite indication than that of tightness of the vessel.

Let us now return to the physics of the circulation. It is usually said—as, for example, by Sir Lauder Brunton but a few months ago—that "arteries which lose their elasticity in old age offer an increased resistance to the blood stream and as a result the heart hypertrophies," this eminent observer holding, I presume, the current opinion, which I have already challenged, that arterial disease comes first and rise of blood pressure consequently Now I have always been ready to admit that the more carefully the principles of physics are studied in respect of living beings the more apparent becomes the difficulty of calculating their validity under the complexities and contingencies which in biological problems overlie and qualify them, but we may feel pretty sure that resistance must depend substantially upon, first, the calibre of the tubes, and secondly, the viscosity of the blood Is it, then, certain that defect of elasticity narrows the bed of the blood stream as a whole? Is it not at least as likely that, on the whole, it may widen it? If in some areas an obliterative process prevail, in others distension may make up for it, and the mean capacity of the channels at any rate may not be diminished [4] Clinical observation of the cases of extreme arterial deterioration without rise of pressure to which I have already referred impresses this opinion upon me. If any chronic arterial disease narrows the bed of the circulating blood surely it is the syphilitic. Now this manifestation of syphilis often occurs in young, active, and temperate men, and in many of these arterial pressure does not rise, as I have had occasion to ascertain in two or three cases observed continuously for many years—in one case for the last 19 years of the patient's life, beginning at the age of 31 and ending with death by aneurysm of the aorta at 50 In him cerebral symptoms had been distinct ten years before his death, and were wholly removed, though every superficial artery was thick. In another case of Jacksonian epilepsy, due to syphilitic arterial disease, the blood pressure was normal during years of occasional observations, and so on of many other such cases.

Omitting, then the rarer arterial diseases, such as obliterative arteritis, neuritic arteritis, and periarteritis nodosa, I suggest three classes of so-called "arteriosclerosis" 1. The involutionary—common in old people, often hereditary, not necessarily or usually associated with rise of arterial pressure, the nature of which, intrinsic or extrinsic, is unknown, but does not lie in high living This kind may be vaguely referred to the "faltering rheums of age." 2. The mechanical—the result of long persisting high blood pressure of whatsoever origin. 3 The toxic—resulting from such causes as lead, alcohol, or syphilis, usually met with in younger persons in some of whom the pressure rises, in others not.

I must now undertake the formidable task of meeting in the gate those many opponents who will tell me that the cases of rising arterial pressure which I have cited are virtually, if not obviously cases of granular kidney, or, at least, to notice for a moment the current phrase, "renal inadequacy" This equivocal phrase, introduced by Sir Andrew Clark in—I venture to think—one of the less successful essays of this sagacious physician, suggests notions founded, as yet at any rate, on no positive facts or reasons, and it lends itself too readily on the one hand to those hollow explanations which are a snare to us, and on the other to the inexorable dictations of the deadhouse. In a recent thesis of considerable merit one of my graduates tried to convince me of the secret influence of granular kidney in arterial disease by imperfectly we had availed ourselves of this capacity of the instrument we may learn from the remarkable treatise on "The Pulse" published but a few months ago by Dr James Mackenzie. Unfortunately the sphygmograph, valuable as it is, when handled by those who are well aware of its limits, in the record of modes, forms, and distributions of pressure, cannot measure positive pressures For many years, therefore, until lately when pressure gauges or sphygmometers of some trustworthiness were put into our hands,[2] I have had to compare arterial pressures as best I could with the practised and attentive finger and to go without units and records. Thus, unsupported by permanent numerical computations, I found it a difficult task to convince my brethren of the importance even of approximate estimates.

---

[4] Sir Richard Douglas Powell (THE LANCET Jan 24th 1903) urges his thesis that the high pressure may be and is maintained by arterial constriction. In THE LANCET for Jan. 31st I ventured with the utmost respect to contest this hypothesis.

Arterial pressures vary very widely If I lift a chair from the ground my arterial pressure may rise 20 per cent and fall again as rapidly as I come to rest. During the use of the sphygmometer, if the patient be not cautioned against contracting his muscles—if, for instance, he be seated in a cramped position—the pressure may fluctuate considerably On a certain occasion I observed a high pressure in a patient in whom a high rate was not anticipated. No fault was found in the parts or arrangements of the instrument, and a second inflation revealed a still exorbitant though a lower rate, a third but a few minutes later registered an ordinary rate of about 120 mm. Hg, and remained steady about this figure. The previous excess I should still have attributed to some experimental fallacy, had not the patient, as [I put the instrument aside, said to me that he had feared from it a violent electric shock, such as one which many years before at a fair had put him in an agony which he had never forgotten As the shock did not occur he was reassured, and the pressure fell. In patients who enter upon a consultation with acute anxiety of mind the pressure at first is often excessive. When close accuracy is of importance it is well then to take two observations, one as the patient undresses, another, after all other physical examination, before he puts on his coat. The large majority of my observations are taken upon the patient seated easily at my table, it is better to keep to a uniform method, and in private practice this position is more convenient than recumbency Observations on patients in bed rule rather lower, but in my practice they have been comparatively few

With Hill and Barnard's sphygmometer the pressures of adults vary from 95 to 105 mm. Hg in temperate young men much occupied with athletic exercises, to 250 mm Hg (the highest figure in the scale) in disease,—as, for example, in Bright's disease.[3] Between these extremes every degree of variation may be found. I often apply the instrument in cases of life insurance, and in healthy men in middle life it should not record more than 120 mm Hg I have never applied it to a healthy woman nor to a child, but by the finger I have often noted high arterial pressure in children.

In sufferers from arterio sclerosis—I use the name arterio sclerosis loosely for present convenience—exorbitant pressures are often but by no means constantly found. Between disease of the arterial tree and blood pressure there is no direct relation, in arterial disease, even in the extreme degree of it, normal or relatively low pressures are commonly observed but I often notice that in cases of arterial degeneration the reading extends uniformly over a wider range of the scale—say over 15 or 20 units, in which cases I record the mean figure and the extremes. In denying that elevation of blood pressure depends directly upon arterio-sclerosis I have stood alone for some years, against the high authority of von Basch and many others, but I think that some recent observers now admit the validity of my contradiction, and the matter is one of cardinal importance. So far as intermittent observations are to be trusted, I repeat that pressure may be, and often is, low throughout the course of arterial degeneration, [or, again, having been high, it may fall, though of course, in some elderly persons with arterial decay occasional transient attacks of high pressure, such as occur at times in all of us, may be observed I need not add that a considerable and persistent fall late in a case, a fall not a result of treatment and not coincident with general amelioration, usually signifies heart failure and presages death within a few months, for it is remarkable how long high pressures are maintained, even when the dilated and overwrought heart is labouring towards the end of its day When the subject of arterio sclerosis begins to be short of breath he has entered upon the last stage of his pilgrimage.

If, then, arterial degeneration be a *vera causa* of elevation of blood pressure its effects may be and often are so modified by incidental and coöperative conditions as to be negligible In many cases of arterio sclerosis in which the blood pressures are not high, to the best of our knowledge they had never been high. Omitting, then, the rarer arterial diseases, such as obliterative arteritis neuritic arteritis and periarteritis nodosa, I suggest three classes of so-called "arterio-sclerosis" 1. The involutionary—common in old people, often hereditary, not necessarily or usually associated with rise of arterial pressure, the nature of which, intrinsic or extrinsic, is unknown, but does not lie in high living This kind may be vaguely referred to the ‘ faltering rheums of age.” 2. The mechanical—the result of long persisting high blood pressure of whatsoever origin. 3 The toxic—resulting from such causes as lead, alcohol, or syphilis, usually met with in younger persons in some of whom the pressure rises, in others not.

I must now undertake the formidable task of meeting in the gate those many opponents who will tell me that the cases of rising arterial pressure which I have cited are virtually, if not obviously cases of granular kidney, or, at least, to notice for a moment the current phrase, renal inadequacy" This equivocal phrase, introduced by Sir Andrew Clark in—I venture to think—one of the less successful essays of this sagacious physician, suggests notions founded, as yet at any rate, on no positive facts or reasons, and it lends itself too readily on the one hand to those hollow explanations which are a snare to us and on the other to the inexorable dictations of the deadhouse. In a recent thesis of considerable merit one of my graduates tried to convince me of the secret influence of granular kidney in arterial disease by collecting the records of a vast number of necropsies of the kind, and declaring the existence of fibroid changes in the kidneys in 94 per cent. of them. A large part of his list consisted of cases of elderly, and even aged, persons in whom no definite diagnosis of Bright's disease had been made, but in whose dead kidneys a greater or less amount of fibroid deterioration had been detected The list contained also, of course, a large number of cases of granular kidney properly so called with which cardiac arterial disease was as usual associated, with these last we have no further concern.[5]

---

[4] Sir Richard Douglas Powell (THE LANCET Jan. [illegible], 1903) urges his thesis that the high pressure may be and is maintained by arterial constriction. In THE LANCET for Jan. 31st I ventured with the utmost respect to contest this hypothesis.

It is impossible at this hour to enter upon the pathology of the fibroid deteriorations found in the kidneys, no less than in many or most other organs, of old subjects, but I must briefly indicate my opinion that this process has little or nothing in common with that of granular kidney proper This fibroid deterioration is a partial atrophy, or a factor of an atrophy, and is consistent and generally associated with a large remnant of normally secreting elements Granular kidney, on the contrary, is the result of a protracted submission of the whole kidney to the action of some poison, often unknown, which has primarily a necrosing effect on the secreting, and an irritating effect upon the connective, elements. This effect is best seen in the acuter cases, as in the kidney of pregnancy, of typhoid fever, of diphtheria, and the like, where the poison is more virulent, the corrosion more acute, and the results less obscured by irritation and by the attempted processes of repair

And I must appeal again from the deadhouse to clinical observation chronic Bright's disease is a malady with features of its own such as headache, nausea, anæmia, retinitis, and so forth, moreover, its mean incidence falls at a somewhat earlier age than that of the malady I am discussing Among its features are undoubtedly high arterial pressure and the baneful consequence of cardio-arterial strain, but leaving aside for the moment the quality of the blood, the state of the retina, and other characteristic symptoms a careful supervision of the urine alone will distinguish Bright's disease if, in some obscure cases, not on a single examination, yet certainly after some days' vigilance. I am not concerned to confine myself to well marked Bright's disease, I am ready to assume that the process, especially in the elderly, may be so chronic as to present its symptoms in a larval shape, yet even in cases so slow so insidious, a careful study of the urine will tell us if the case turns upon the kidneys. In the kidneys of old persons undergoing some involutionary change, there is secreting area enough to clear the system. Dr Rose Bradford's ablation experiments support our experience herein, and pathological methods rarely exhibit in these cases a deep intrusion of alien tissue During life albumin, at times abundant, will rarely prove to be absent for many days together Even in the early stages of disease we may distinguish the high arterial pressure of renal origin from that not of renal origin, as in the latter albumin is absent, but in the former, if not constantly, is frequently present. Granular casts, again, absent in the non renal cases, in the renal are not infrequent. Such a case as the following is no uncommon one a man between 50 and 60 years of age presents himself with a big heart thick and tortuous arteries, a blood pressure of from 230 to 240 mm. Hg, and some œdema of the lungs. Death may be staved off for a while but his condition is perilous. Now, if ever, his urine should present evidences of "renal inadequacy" He passes for us, however, a small quantity, high in colour, of normal or high specific gravity, which thickens as it cools, and may paint the bottom of the pot. There may or may not be a little albumin in it, but, even after spinning, no casts or but a few hyaline casts are discovered. On subsequent observation during alterative treatment a week's urine proves to be up to the normal mean of solid excretion, or the fall in urea corresponds with a restriction of the diet, a condition often forgotten. After death we find the kidneys tough, the capsule a little adherent, the surface a little rough, and presenting some shallow intrusion of fibre into the parenchyma, and we find evidences of fibroid deterioration not only in the heart and arteries but in many other parts also Now, I have watched such cases from beginning to end for many years, and in not a few of them I have witnessed all the phases of the malady in the same individual the lesson I have learned from them and would impress upon others is that the first deviation from health is not arterial disease but rise of blood pressure, the arterial disease being secondary and due to strain, that although this malady has, in common with Bright's disease, the feature of a rise of blood pressure and consequent cardio-arterial strain, it is essentially distinct from the latter and has no tendency to drift into it, that on its first appearance this arterial plethora is remediable—nay, on its second or even third appearance it may be driven away, and that even when somewhat advanced, if the tendency may not be eradicated, it may under due regulation of life and medicine be held in check. In an elderly man, or in one of "gouty" family, a week's high living will produce the state, and a few days fasting and blue pill will dispel it.

On the causes of the process I have described I have little to say worth your hearing If you call it gouty you will give me little help Gout is a clinical series, in the type of which inflammation of a joint or joints must be included, and in which rise of arterial pressure is not the rule or, if present, is incidental. I find that in many men badly afflicted by recurrent gout, if free from kidney disease and of temperate habits, rise of arterial pressure does not occur, their vessels remain fairly healthy and they attain to ripeness of years. Persons accused of "suppressed gout" are found in every consulting room, their only common feature seems to be the absence of the chief characteristic of gout—namely, arthritis, they solicit it, they pray for it—for they believe that it would resolve their disorders, but they pray in vain. On the nature of overt gout he is a bold man who expresses a positive opinion, suppressed gout I believe to be the label of a heterogeneous bundle of maladies, many of which have little or nothing in common, but among them my arterial plethora plays a large part. That this malady has any part in gout, or gout in any part in it, I have no knowledge or surmise, their association in the individual seems to me not to exceed the ratio of mere coincidence, though gout seems to have more than this ratio in the family history of such patients Arterial plethora is not a common disease in the poor or in persons who live actively and eat and drink sparingly

And this brings me to the second physical factor of blood pressure—namely, the viscosity of the blood. For nearly ten years past I have endeavoured, but with much mishap, to estimate this factor Time after time the subject has been agreed upon for a graduation thesis, and as often the research has broken down for one reason or another My suggestion is that, in the simple cases of rising arterial pressure which I am discussing, the blood is above the normal viscosity, viscosity is not the same quality as specific gravity, nor do they necessarily vary together And I speak of the viscosity of the blood as a whole, *not of the plasma*. Dr A. Haig assures me that in gout the blood does stick in the finer vessels, because of admixture of uric acid, and he most kindly sent to me a little instrument by which this lagging is to be demonstrated, an instrument of which as yet I have had insufficient experience. The injection of uric acid into the blood of animals raises the arterial pressure, if at all, very transiently That we may have to do with some of the purin bodies, lately investigated by Dr Walker Hall and others, is not unlikely, that uric acid is the offending element I have not satisfied myself In some persons faulty metabolism, without extrinsic poison, may set up granular kidney, and my contention that under mental distress a fault of this kind is apt to arise and to have this issue, is, I think, now generally admitted to be true, in other persons some such perversion, sparing the kidney, seems primarily and of itself to set up resistance in the periphery of the circulation, and thus to lead to strain of the arterial tree. It may be that the formation of "anti substances" to protect the system against the toxins of digestion is not equally active in all persons The disposition to fibrosis, which is found generally, if not universally, in the tissues of such patients may be a direct consequence of the perverted juices, or may be a feature of slow atrophy due to failing blood streams. The vasa vasorum suffer early, and it is as yet impossible to say what part, whether as cause or consequence, these tiny channels play in the deterioration of the larger vessels which they should nourish Of these vasa vasorum the coronary arteries are the chief, here, however, we see to our surprise—as I urged more at length in my Lane lectures of

---

[5] Sir William Broadbent at the meeting of the society and Dr A Morison (THE LANCET, Jan 28th 1903) agreed with me that renal cases may be distinguished from the cases I have now under consideration.

1895 and elsewhere—that the heart can hypertrophy, and in substantial measure of time and degree retain its hypertrophy, when its coronary arteries have both of them been very gradually but completely occluded

On treatment I can now touch only in the briefest way. If, as I believe, one main cause of rising arterial pressure in middle life is excess of feeding—that is to say, of food in excess of work and excretion—the remedy obviously lies in prevention. That alcohol, apart from excess of food, will produce the condition I am not sure—I think not, on the other hand, I do feel sure that with such excess it is a potent ally, as in its alliance with arsenic, it seems to prepare the way by lowering tissue resistance. We see a few old men who, usually of lean habit and inheriting longevity, are endowed with enormous and persistent energy of mind and body, and who have never denied themselves meat or drink, yet at threescore and ten or fourscore years have good arteries and a moderate blood pressure, but such men are few, in most persons, as life slows down, the powers of expenditure and excretion fall within much narrower limits The ordinary man must be warned—say as he passes the age of 40 years—to keep up muscular exercise in the open air, and to control his appetite Many, I should say most, men eat and drink far more than they need for the day's work, they are supplied with food generously, without hunting for it, and annual blood letting has gone out of fashion. As soon as high pressure becomes manifest rigorous diet, deobstruent remedies, and exercise such as cautious hill climbing under the careful regulation of the physician, are necessary, and necessary not only during a Homburg month and its "after cure," but also for the rest of the patient's life. Catch him early and he is quite curable, let him drift and cure may be out of reach

My purpose to-day is fulfilled if I can impress upon my hearers the importance *obstare principiis* It is in such means as these that we see the value of the Chinese practice of paying the physician only during the days of health, though the method should be supplemented by a provision for the recovery of damages from the patient who disobeys our prescriptions.

Cambridge

REPORT ON THE INFLUENCE OF SANITATION IN CHECKING ENTERIC FEVER AND DYSENTERY AT HARRISMITH, ORANGE RIVER COLONY, SOUTH AFRICA, IN THE YEARS 1901 AND 1902

BY R. M. LE HUNTE COOPER, M.D B.S LOND, M R C S. ENG,
CAPTAIN ROYAL ARMY MEDICAL CORPS

THE following report has for its chief object the demonstration of the remarkable results attained by sanitation—more especially directed towards preventing the spread of infection by flies—in controlling both the extent and virulence of the above diseases during the fever season of 1901 and 1902 The 8th Division marched into Harrismith on August 7th, 1900, and the temporary hospital, from which all the earlier returns have been taken, was first opened on August 26th, 1900

In previous years Harrismith had always suffered from enteric fever and dysentery during the summer months. While a certain amount of dysentery was prevalent all the year round the enteric fever season was almost entirely confined to the period between the end of October and the middle of April. With the exception of the year 1890 both these diseases had been of a mild type, and it was not until the recent war that their virulence increased to such an alarming extent Although the epidemic of 1890 was severe the civilian practitioners of the town told me that it could not compare with that of the season of 1900 or that of 1901.

The two seasons compared in the following statistics are (1) that from the last week in August, 1900, to the end of April, 1901, and (2) that from the last week in August, 1901, to the end of April, 1902. For the sake of brevity the first will be called "Season A," and the second "Season B"

POSSIBLE CAUSES OF ERROR IN THE TABLES.

1. A certain element of error with regard to the fatality of the diseases in question must necessarily enter into the statistics taken from the military hospitals owing to the number of cases transferred down country whose subsequent death or recovery it has been impossible to ascertain, but this applies equally to both seasons and hence cannot materially affect conclusions drawn from a comparison between them.

2 Special notification of cases locally contracted was not instituted till April, 1901, and it has therefore been necessary to divide those contracted in Season A into (*a*) direct admissions and (*b*) cases transferred from other hospitals Every endeavour has been made to ascertain whether any of the direct admissions had been contracted on trek, as, for example, in those instances in which men have been admitted with enteric fever or dysentery a few days after arrival in Harrismith On the other hand, a certain number of cases shown as transferred from other hospitals were from field hospitals which had remained for some time in Harrismith and were consequently of local origin. As at this time the cases contracted on trek were invariably first admitted to a field hospital and then transferred to the temporary hospital at Harrismith, the greatest care being taken to distinguish between "direct admissions" and "transfers," the error arising from the above two sources is so slight that for the sake of comparison it may be disregarded.

3 During Season A a certain number of cases which were probably enteric fever were diagnosed and transferred as simple continued fever, whereas in Season B most of these cases were recognised to be abortive enteric fever and were diagnosed as such.

ARRANGEMENT OF THE TABLES

To give a comprehensive view of the diseases in the following tables the total number of cases admitted has been shown in the centre, where they were contracted locally or on trek, on the left side, and their ultimate disposal, either by return to duty, by transference, or by death, on the right side.

It will be seen that in Season A from August 26th to the end of September 1900, there were only 15 cases of enteric fever and 16 cases of dysentery and that none of these were fatal Indeed, as many as three patients suffering from enteric fever and 15 suffering from dysentery were returned to duty, the remainder being transferred down country In October, however, the number of cases of enteric fever and dysentery had an increase over the previous month of two and of 10 respectively and the commencing virulence of the former disease is shown by the fact that the patients in two cases died. In November the totals suddenly rose to 68 cases of enteric fever, of which 11 patients died, and of 45 of dysentery, of which one patient died. In December the epidemic reached its maximum with regard to the virulence, the number of cases of enteric fever being 121, of which 28 patients died, and 45 of dysentery, of which three patients died In January, 1901, the maximum number of admissions was reached though the total number of deaths was nine less than in the previous month The number of cases of enteric fever admitted was 184 of which 19 patients died, and 36 of dysentery, of which three patients died. February showed a drop both in the admissions and deaths, the patients admitted suffering from enteric fever being 120 of whom 14 died, and from dysentery 28, of whom one patient died In March the number of admissions for enteric fever increased by one and the deaths by three over those of the previous month, while the patients admitted for dysentery were one less, there was one death from this disease, as in February April showed a further drop to 114 cases of enteric fever, of which eight patients died while the cases of dysentery increased to 69, of which one patient died A summary of the tables shows for this season a total of 756 cases of enteric fever, of which 631 were of local origin, and 260 cases of dysentery, of which 219 were of local origin The fact, however which gives the best idea of the severity of the epidemic is that the deaths amounted to 99 from enteric fever, of which 81 cases were of local origin, and to 10 from dysentery, of which nine cases were of local origin.

CAUSE OF THE EPIDEMIC

When seeking to account for the appalling spread of this epidemic it became a question of vital importance to discover the mode of dissemination of the germs. One naturally turned first of all to the water supply This was obtained from the Platberg, a large hill lying close to the town and with an extent of surface, approximately, of five square miles The water, after percolating through the soil, issued from the side of the hill in springs Several of the streams formed by these springs, extending over an area of about two square miles, were made to converge towards the water tanks, which latter were fenced in to protect them from the encroachment of animals. The whole catchment area was not fenced in at the time of my investigation and there was, therefore a risk of contamination of the streams from this source, though, as there were but few animals grazing on the slopes of the Platberg, the danger could not be accounted as very great. Besides which, the water, when chemically and bacteriologically examined, was invariably found pure I ascertained from the town clerk that in previous years, when peace prevailed, it had been usual to graze a large number of cattle over this ground, yet former epidemics had been trifling in comparison with the one in question Hence, one was compelled to seek elsewhere for a cause. Fresh milk at this time was very scarce and tinned milk took its place to a large extent. Those inhabitants of the town who used fresh milk generally obtained it from a cow of their own, the troops, who were the chief sufferers, being supplied wholly with tinned milk, so that this source of infection had to be put out of court

It will be well to consider here the condition of the town and garrison at this time. Since its construction the town had been for the most part occupied by Boers whose ideas of general cleanliness might be taken as a negligible quantity Refuse had been allowed to collect in back yards and waste ground to such an extent that the town was a veritable rubbish bin and in addition those inhabitants who had abandoned their houses at the commencement and during the progress of hostilities had neglected to have their latrines cleaned and locked up before they left Several of these contained excreta several months old and kept in the best possible condition for breeding germs Natives and others finding them open had used them from time to time, so that their general filthy condition can be better imagined than described. Various units were camped in the vicinity of the town and at this time their ideas of sanitation were primitive in the extreme They were using open latrine trenches, with little or no attempt to keep the excreta covered and the men were most probably in the habit of urinating on the ground. I make this latter statement because I have found by practical experience that, unless special buckets are placed close to the men's tents at night, it is quite impossible to prevent the ground being polluted. The above condition of camps prevailed in spite of efforts made to remedy it, simply because there had been no time to institute a definite hygienic system. I found that it took months to train units into carrying out a systematic sanitary routine Columns would come into Harrismith for supplies from time to time and would camp within the outposts. These columns either considered sanitary measures superfluous or else did not consider them at all, for it was usual to find latrines uncovered and quantities of refuse on the ground after the columns had left. Native locations existed close to the town which were under little or no supervision, hence excreta and refuse of all kinds could be seen in the dongas and on the banks of spruits adjacent to these locations. As can be well understood, all this tended towards the breeding and maintenance of enormous quantities of flies which were constantly flying backwards and forwards between the excreta and food Indeed, their numbers were so great that one could only account for the fact that every one was not infected by supposing that many had become immune through constantly imbibing small doses of the poison.

At this time I was in command of a half field hospital and I found that whenever our column put into Harrismith for a few days for supplies numbers of the men suffered from diarrhœa and muco enteritis which usually came on from two to three days after our first camping near the town This was of such frequent occurrence that we were only too glad to start off on trek again. I am fully convinced in my own mind that this sickness was produced by the direct contamination of the food with fæcal matter conveyed by flies. To me it is quite conceivable that if flies can convey pollen from one flower to another they can also convey particles containing germs I have little doubt that the common house flies take an active part in fertilisation, as I have myself noticed that several species of flowers are visited by these insects. The recent experiments of Major C H. Hale, D S O, R.A M C, at Ficksburg lend confirmation to the theory of infection by flies Lime was sprinkled over an open latrine and a piece of raw meat was placed within a few yards of it It was found that within a comparatively short space of time the meat was covered with a layer of lime, this having been conveyed by the flies from the latrine to the meat. One of the arguments with which I have been assailed is that the town was as filthy and the flies were probably as many as in former years, yet that no previous epidemic was so severe. My answer to this is that it is doubtful if the town was ever so filthy before, for, as explained above, many of the inhabitants had left in a hurry, without attending to sanitary matters before leaving, and it was not until the present war that camps had existed all round the town But even leaving this out of account I do not claim that the flies determine the virulence so much as the *spread* of infection Once given the introduction to the town of a virulent form of enteric fever by the troops—and it is a recognised fact that this fever is never so virulent as during a campaign—the existing conditions of the town were such as to favour its spread by the agency of flies.

Harrismith, like most towns in South Africa, suffers severely from dust storms and it has been suggested that infection is carried by such means. It is only natural to suppose that the germs can be thus conveyed, but I do not think that in this particular epidemic this mode of infection was the chief one. It must be considered that for infection to be conveyed in this way it is necessary for the excreta, or other germ containing medium, to be first dried by the sun and air and so reduced to minute particles capable of being disseminated by the wind, but surely this very process of desiccation which it has gone through must have either killed, or at any rate devitalised, the germs, to a large extent, by the sterilising action of the sun. On the other hand, the flies are constantly flying to and fro between the infected matter in its fresh state and the food so that it is only reasonable to suppose that this source of infection must be far the more potent of the two

SANITARY PRECAUTIONS.

The sanitary measures adopted at Harrismith, though they include the usual precautions commonly recognised under this head, were in the main devoted to preventing the contamination of food with germs conveyed by flies and the possible infection by dust. These measures naturally came under three headings—viz. (1) the protection of excreta from flies, (2) the destruction of flies and prevention of their breeding, and (3) the protection of all kinds of food from flies.

1 *The protection of excreta from flies* —For this purpose it became necessary to employ some covering which would mechanically protect the excreta. If one could have been certain that a thick layer of dry earth would always be kept over the excreta and that the greatest care would be taken to exclude flies when the pans were being emptied, one would have been disposed to employ this method as being the most economical but knowing the difficulties in this respect and taking into consideration the virulence of the germs with which one had to deal, it became clear that some form of disinfectant which would at once serve the double function of keeping off flies and devitalising or destroying the germs should be employed. In choosing a suitable disinfectant for use with troops, it seemed to me to be a very important consideration to choose one which, in addition to having the above qualifications, would at the same time be easily visible to the inspecting sanitary or other officer and so would prevent the men from saying that they had used it when they had not All liquid disinfectants had the disadvantage that they sank to the bottom of the pans and in consequence neither formed a mechanical protecting layer nor left any visible evidence of their recent use. Powders, on the other hand, had neither of these disadvantages Hence, it was finally decided to employ a dry disinfectant and the one which seemed especially to meet the requirements was chloride of lime. Its odour kept the flies off more than ordinary lime and being white it could always be seen after use These advantages applied equally when it was used in excreta tubs and in urine tubs, for in the latter case it formed a frothy layer on the surface of the liquid The orders issued with regard to the use

of this disinfectant were to the effect that pioneers should be appointed at each camp and post to go round five or six times a day to see that the excreta and refuse were always kept covered and that the disinfectant was also used in the urine tubs. The men were directed to use the disinfectant freely before leaving the latrine, notices being placed in the latrines to this effect, and the non commissioned officers in charge of the posts were made personally responsible for the strict observance of these orders. Attention was directed to the question of disinfecting the urine as well as the fæces, for it seemed conceivable that infection might be conveyed by flies from ground on which infected urine had been spilt when the urine tubs were being emptied I found that as new units arrived it took from two to three months to drill them into anything approaching perfection in the carrying out of the above precautions, but the condition of the Harrismith outposts and camps at the time of writing was such that one may visit any number of these and yet rarely find any excreta or refuse visible. Corrugated iron latrine sheds were constructed for the excreta buckets. These, by protecting the contents of the pans from the light, materially assisted in keeping off the flies, as the latter will not so readily feed in the dark. An additional advantage was that stained latrine paper was prevented from being blown about. Prior to the introduction of these sheds it was no uncommon sight to see quantities of this paper being blown by the wind from place to place, especially when high winds prevailed

2 *The destruction of flies and prevention of their breeding* —Tons of refuse which had no doubt formed breeding grounds for these insects were removed from the town and its precincts In the case of the town this was accomplished chiefly by the aid of the military native prisoners, as the municipality could not afford to keep natives for this purpose, while the ground surrounding the town was kept clean by a sanitary corps specially formed for this purpose In addition, the inhabitants were encouraged to cultivate their waste ground as far as possible, as it was found that the soil which had been left undisturbed for some time contained quantities of eggs and young flies just hatching out. Special notices were distributed throughout the town calling attention to the danger of infection being conveyed by flies and the inhabitants were urged to do all in their power to destroy these insects It was found that the only satisfactory method for this purpose was to use Keating's powder This was dusted at night over the walls of kitchens and other rooms in which the flies tended to collect and also over the window sills during the day In this way, with the expenditure of comparatively little time and trouble, it was possible to destroy thousands of the insects daily in each house.

3 *The protection of all kinds of food from flies* —Meat safes made of perforated zinc were erected at every camp and post, and units were encouraged to construct fly tight boxes for the other rations such as bread and vegetables. It was also recommended that these boxes should be taken down to the supply depôt and the rations placed under cover as soon as they were drawn and so conveyed back to the unit with no danger of contamination during transit. Notices were distributed throughout the town to the same effect and the inhabitants were advised to protect their houses by fixing gauze screens over the windows. The best form of screen was found to be one consisting of a metallic gauze of fine mesh fixed to a wooden frame which was hinged to the outside supports of each window To clear a room of flies all that was necessary was to flick the walls with a fly wisp or cloth. The disturbed flies invariably settled on the gauze screen which was then opened and the flies were brushed out The closing of the screen again prevented other flies from entering

Other sanitary precautions were taken which, though they were not specially directed towards preventing infection from being conveyed by flies, in many cases indirectly assisted towards this end

Native sanitary corps —First and foremost among these must certainly be placed the formation of the native sanitary corps mentioned above The greatest possible difficulty was experienced at first in having carcasses and refuse removed promptly, owing to the scarcity of wagons and the fact that natives were only occasionally available for the work It often occurred that several weeks would elapse after these had been reported before they were removed this being especially the case during epidemics of rinderpest from which numbers of cattle died at different times The carcasses would be sometimes left so long that they became too decayed to allow of their removal and in consequence they often had to be buried where they lay This was especially objectionable when they had died in the vicinity of camps or on ground likely to be subsequently used for camping purposes, to say nothing of the unpleasantness caused by the foul odours which had been given off during the process of putrefaction Hence, it became imperative that some systematic removal and burial of carcasses and refuse should be inaugurated and to meet the difficulty a native sanitary corps was formed. This had for its *personnel* a combatant officer, a non-commissioned officer, three privates a conductor, an overseer, and 100 natives It was provided with 10 wagons, two Scotch carts, and two teams of oxen for drag purposes. Prior to the formation of this corps it had been customary for all units to remove their camp refuse in their own wagons which were at other times used to convey rations This formed a great element of danger from possible contamination of the food, as the non-commissioned officer in charge of the wagon, when drawing supplies, could not be trusted effectually to protect the rations. When the sanitary corps was formed this danger ceased, as the work of removal of camp refuse was undertaken by the corps as one of its routine duties.

Water —As explained above, the municipal water reservoirs were protected by a wire fencing at the time of the British occupation of the town, but the catchment area as a whole was not fenced in. The importance of taking this latter precaution without delay was pointed out by the principal medical officer of the 8th division, but many objections were raised to the scheme, the chief of these being (1) the difficulty of deciding whether this should be undertaken by the military or by the municipality , (2) the cost, which it was found would be very heavy, as several miles of fencing were required , and (3) the question of labour Colonel J L Notter, Professor of Hygiene, inspected the water supply on March 4th, 1901, and, seeing the danger of the water being polluted by cattle, recommended the construction of filter beds, but the objections raised to the first scheme applied far more to this, as the cost and labour necessary in this case were infinitely greater than in the former Early in November the whole of this area, from the reservoirs up to the Platberg, was inclosed and the Harrismith water supply could then be said to compare favourably with any in South Africa Although this practically raised the water above suspicion strict orders were nevertheless issued to the effect that all water used for drinking purposes or for washing plates, vegetables, &c , was to be boiled before being used and that water carts and tanks were to be cleaned out once a week with a solution of potassium permanganate. The same precautions were also taken with the men s water bottles. The use of Berkefeld filters was also encouraged as an additional precaution, but only a few of these were available

Ultimate disposal of excreta and refuse —As the various outposts and many of the camps round Harrismith were permanent it became in the highest degree desirable to prevent the ground from becoming contaminated more than was absolutely necessary With this object in view a pail system was adopted and arrangements were made that both the soil buckets and urine tubs should be emptied at least once a day Not a single outpost, however distant or difficult of access, was without this provision The work of removal was given over to a civilian contractor who arranged for the transport of the excreta, by means of tank carts, to a piece of ground lying well outside the town Urine tubs were ordered to be placed close to the men s tents at night, to prevent the pollution of the ground This allowed of the urine being disinfected and eliminated the danger which would have followed its drying on the ground and so infecting the dust.

Precautions at blockhouses —Precautions were also taken at the various blockhouses which formed the outposts of Harrismith. It was found when these blockhouses were first constructed that a layer of dust, consisting chiefly of dry earth, invariably formed on the floors and that this rendered it impossible to keep the ground clean It was therefore decided that all the blockhouses should be floored with a mixture of ant heap and water This, in drying, formed a hard level surface which could be easily brushed. It was also found that by frequently whitewashing the beams and interior of the blockhouses with a mixture containing chloride of lime the flies could be kept away to a very considerable extent

Notification of disease —A system was introduced by which the resident magistrate rendered a weekly report to me of the name and residence of any civilian suffering from enteric fever or dysentery, this information being regularly notified to him by the civilian practitioners of the town. On receipt of this report I visited the house and recommended any sanitary measures which I considered necessary to prevent the spread of the disease. In addition, I was also notified of the number of cases of these diseases in the Boer refugee camp, the report being sent by the superintendent through the resident magistrate. In No. 19 stationary hospital each case was most carefully investigated to ascertain whether it had been contracted locally or on trek. In the former case a report was sent to me giving the name of the patient and the camp from which he had been admitted. I visited these camps in a like manner and if the tent previously occupied by the man could be identified it was taken down, scrubbed, and moved to a new site and the ground on which it had been standing was then limed and left to the action of the sun and air for some time before being again used for camping purposes. Inquiries were always made to ascertain if the patient had been in the habit of frequenting any particular eating house in the town, but I never succeeded in tracing any particular case to this origin.

Removal of the hospital.—I think one may justifiably include this under the head of "sanitary measures." When the town was first occupied the school house and church, as being the most suitable buildings, were formed into a temporary hospital and remained as such from August 26th, 1900, to February, 1901, when No. 19 stationary hospital was sufficiently advanced in construction to allow of patients being transferred to it. This latter hospital consisted of wooden huts and marquees and was placed half a mile outside the town, so that there was far less danger of infection being conveyed by flies from the hospital to the town after the removal of the patients to this distance than was the case formerly.

The above particulars will give a fair idea of the general principles which were carried out. As to their efficacy Table I. will speak for itself.

CASES DURING SEASONS A AND B (TABLE I.)

Regarding the table of Season A and Season B I wish especially to draw attention to the column headed "contracted locally." The difference between the two years will be at once apparent.

The relative number of locally contracted cases in the two seasons was as follows:—Season A: Enteric fever, 631; and dysentery, 219. Season B: Enteric fever, 62; and dysentery, 30. Yet the total cases admitted were greater by 321 and 187 respectively in Season B than in Season A.

TABLE I.—*Showing the Total Number of Cases of Enteric Fever and Dysentery admitted.*

SEASON A.—*From August, 1900, to April, 1901.*

April	Enteric fever	17	119	136	20	156	7
	Dysentery	2	40	42	20	26	4
Totals	Enteric fever	62	1015	1077	65	765	41
	Dysentery	30	437	467	163	262	10

A comparison of the number of cases admitted during the various months shows that in Season A the month with the largest number of admissions for enteric fever was January and that with the largest number for dysentery was April, whereas in Season B the months showing the largest number of admissions were February and January respectively. Very little can be deduced from this, as the number admitted in any one month was necessarily influenced by the number of columns operating in the neighbourhood, which was by no means a constant quantity, but it is satisfactory to note that, although in Season A during the months mentioned most of the admissions for enteric fever and all those for dysentery were locally contracted, in Season B nearly all the cases were contracted on the veldt. In the locally contracted cases which arose in the hospital itself the patients were orderlies actually attending on the sick, and the latter were men who had been admitted to the convalescent camp from the hospital only a few days before developing symptoms of enteric fever and who had no doubt caught the infection in the hospital. As these cases were beyond the influence of sanitary measures applied to the garrison at large they should, strictly speaking, have been eliminated from this report, but it was impossible to strike out cases contracted in this way in Season A as no record was kept of these, so that for the sake of comparison they had also to be included in the figures of locally contracted cases in Season B. It will be seen that of the 62 local cases of enteric fever 1 per cent. was contracted in the hospital and 2 per cent. were contracted in the convalescent camp and of the 30 local cases of dysentery two were contracted in the hospital, leaving only 41 cases of enteric fever and 28 cases of dysentery for the garrison itself.

DEATHS (TABLES II. AND III.)

The most significant figures are to be found in Tables II. and III., for they show that although no less than 81 of the 99 deaths which occurred from enteric fever in Season A were of cases locally contracted *not a single locally contracted case died during Season B*. Similarly, with dysentery in Season A nine of the 10 deaths were locally contracted,

TABLE IV —*Showing the Number of Civil Cases of Enteric Fever treated by Private Practitioners in Harrismith* *

—	No of cases.	Deaths
Season A	145	10
Season B	54	2

* No accurate returns of deaths from dysentery could be obtained

while *no local case died in Season B*[1] This proves that the virulence of the epidemic in Harrismith had decreased in a very remarkable degree in spite of the fact that the disease was very severe on the veldt.

PERCENTAGE OF DEATHS.

Enteric fever —The percentage of deaths on the total cases of enteric fever dropped from 11 7 per cent. in Season A to 3 8 *per cent.* in Season B This coupled with the fact that the percentage of deaths from cases contracted on trek in Season B was between a third and a quarter of that of Season A, shows that the epidemic as a whole, affecting individuals both on the veldt and in the town, was undoubtedly less severe in Season B than in Season A, but in the case of the locally contracted cases the percentage of deaths fell to 0 per cent. in Season B *as against* 11 1 *per cent. in Season A*—a far greater fall in proportion and one which may reasonably be attributed to the sanitary precautions taken. In other words, the difference of severity between the two seasons was remarkably greater in the cases locally treated than in those contracted on the veldt

This is at once an answer to the argument that the reason for the lessened severity of the fever in Harrismith in Season B was due to this disease tending to vary, being less severe in some years than in others, for it is apparent that although the severity of the total epidemic was less, the disease in Harrismith was of a far less severe type than that on the veldt.

Dysentery —The severity of the epidemic of this disease, both on the veldt and in the town, is also shown to be less in Season B than in Season A, the deaths having dropped from 3 6 per cent. *to* 2 1 *per cent*, but this can be shown to be wholly due to the lessened severity of the disease in Harrismith, as the figures show that there was actually a higher mortality on the veldt (2 3 per cent.) in Season B than in Season A (1 6 per cent.) This likewise is an answer to the argument mentioned above

CIVILIANS SUFFERING FROM ENTERIC FEVER (TABLE IV)

As one of the local practitioners did not keep a record during the first season of the number of dysentery cases which he treated I have not been able to obtain statistics of this disease for comparison, so I am only showing the cases of enteric fever It will be seen that in Season A the total number of cases treated was 145, the patients in 10 of which died, while in Season B the total was 54, of which two died.

As these two were the only cases out of the whole garrison and town which died during Season B it will be of interest to see what kind of cases they were, in order to account for their fatal termination. One was that of an old lady who had suffered from asthma for many years and who died from heart failure. The other was that of a child, ten years of age, who died from meningitis complicating the enteric fever

CIRCUMSTANCES ACTING IN ANTAGONISM TO HYGIENIC MEASURES.

There are several of these which in themselves were sufficient to account for the local cases of enteric fever and dysentery during Season B

Boer concentration camp —I looked upon this camp as a very great menace to the health of the garrison and town. Enteric fever and dysentery existed among the refugees in a severe form, and but for the barrier formed by the stringent measures in force they would no doubt have spread beyond the camp Indeed, it is more than probable that several of the local cases were due to germs conveyed in this way This camp was under the civil administration and the general health of the garrison and town so largely depended on its being kept in a sanitary condition that it became necessary for me to inspect it frequently in my capacity of civil sanitary officer I found it impossible to get my recommendations carried out thoroughly, this being specially the case with regard to the protection of the excreta from flies. A few suggestions, however, bore fruit and notably those for the installation of an incinerator for the destruction of infected excreta from the hospital and the thorough disinfection of all hospital linen Although it is almost beyond belief that human beings could become so degraded, it is none the less a fact that women in this camp were known to throw excreta into other women s tents as an act of spite and the sergeant living in the camp informed me that it was no uncommon thing for the Boers to use their tent walls in place of latrine paper From this it can be easily judged how difficult the task of the superintendent must have been to instil cleanly principles into these people and how great was the danger of the spread of disease from this camp during an epidemic.

Natives.—Probably the next greatest menace was from the natives. We have to consider the permanent native locations, and in addition several thousands of native refugees who were brought in from the veldt and camped in the vicinity of the town. My recommendations to the civil authorities were practically ignored, with the result that when Professor Simpson made his inspection I was able to show him human beings living under the most startling insanitary conditions which it would be possible to conceive. It would take up too much space to give all these in detail and it would be unnecessary for the purpose of this report Fortunately the danger was realised in time and these camps were broken up and the natives were sent down the line to other locations near Albertina The work of removal took some months and all this time the town was exposed to danger from this source—a danger which can hardly be overestimated, as many of these natives were suffering from enteric fever and dysentery at this time. It takes some time to accustom natives to the use of latrines and it often happens that, although these are provided for them, they prefer to make their way to some donga or spruit In order to prevent this native policemen were posted over likely dongas and any native caught polluting then was made an example of but it can be readily understood that it was impossible entirely to suppress this evil. As it was not unusual for natives suffering from mild enteric fever or dysentery to refrain for some time from reporting themselves to be sick, the danger from this source can be easily appreciated. One very dangerous habit of the natives which I discovered was that of using stones in lieu of latrine paper At one time it was not unusual to find a latrine full of these stones, any one of which might be covered with pathogenic micro-organisms. I had all these stones regularly removed at the time that the excreta buckets were emptied. Disinfectants were also freely used in these latrines.

Mobile columns —Although units which were camped for some time round the town could be drilled into carrying out systematic sanitary principles it was quite otherwise with those columns which merely stayed in the vicinity of Harrismith for a short time The ground became so fouled by these that recommendations were strongly made to the general officer commanding to the effect that all such columns should be ordered to camp outside the outposts. If it became imperative that such a column should camp within the outposts latrine buckets were supplied to it at once and the sanitary corps cleaned the ground immediately after it had left. Occasionally detachments would be ordered into Harrismith from places such as Tyger's Kloof in which enteric fever or dysentery was prevalent. These were a menace to the whole garrison. Especial care was taken to instil the principles mentioned above into these detachments and the grave consequences which would follow neglect in the carrying out of these were pointed out to them.

---

[1] In case it may be said that the above figures were due to more of the serious cases being transferred in Season B than in the other I may here say that this was not the case, as in both seasons especial care was taken to retain all serious cases until they could undertake the journey without danger

Disposal ground for refuse, carcasses, and excreta —This is unquestionably a very great blot on the hygiene of Harrismith. From its proximity to the river it must necessarily foul the water and it forms an attraction and breeding ground for quantities of flies. Until some more sanitary form of disposal is introduced this will always be a source of danger to health. The questions of changing the site of the ground and of the installation of incinerators has been frequently mooted, only to be overruled by a number of objections which for the time being it was impossible to overcome. It would take up too much space to go into all these in this report, but it may be said that the main difficulty in the way is the lack of municipal funds. I am fully convinced that in years to come, when trees have been planted around the town, when an effective method of disposal of refuse has been introduced, and when the inhabitants have been educated into the carrying out of common sense sanitation there should be no more salubrious spot in South Africa than Harrismith.

In considering the fall in the mortality which occurred in Season B one cannot ignore the fact that the altered hygienic conditions under which the cases were treated in No 19 stationary hospital probably assisted towards this end, but as all cases (both those contracted on the veldt and in the town and garrison) were treated under the same conditions this will in no way affect the fact that the mortality-rate of the cases contracted on the veldt was much higher than that of those contracted in the town and garrison

Stanley gardens, W

A CASE OF ACUTE TETANUS WITH CERTAIN POINTS OF INTEREST

By L. DIMOCK SAUNDERS, M R.C S Eng, L R.C P Lond

THE patient, a man, aged 38 years, was thrown from a dogcart on to a rough bank on Feb 2nd, 1903, and he sustained a somewhat deep and lacerated wound just above the left knee-cap, and several scratches about the hands and face. Within an hour after the accident he was taken to the Salisbury General Infirmary where the wounds were carefully washed and dressed with carbolic lotion and the cavities were stuffed with iodoform gauze He came under my care on the following day and I continued personally to dress the wound which appeared to be making uninterrupted progress towards recovery, the edges of the wound freely granulating and gradually contracting On the 12th everything appeared perfectly satisfactory The patient was cheerful, in good spirits, and made no complaint of any discomfort in the wound. On the afternoon of the 13th word was brought to me that slight difficulty in speaking was noticed. I went immediately to see the patient and I found that there was a distinct change in the voice and in the expression of the face, the masseters and sterno mastoid muscles were becoming tense. He also complained of aching pains in the jaws and shoulders The temperature was normal, the pulse was 60, and the heart sounds and the lung sounds were normal. The teeth could be separated about three-quarters of an inch As the patient was slightly constipated four grains of calomel were given. Antitoxin was immediately telegraphed for and it arrived that night, 10 cubic centimetres being injected into the lumbar region at 11 P M, 15 grains of chloral hydrate were also administered and I ordered him to be given as much of meat jelly essence, beef tea, and milk as he would take. On the 14th at 10 30 A.M the pulse was 96 and the temperature was normal. The teeth could now only be separated about a quarter of an inch. 10 cubic centimetres of antitoxin were injected. Dr H. P Blackmore, who saw the patient with me at 1 P M, confirmed the diagnosis and advised following on with the same treatment. At 9 30 P M 10 cubic centimetres were again injected. The patient was now very restless and the abdominal muscles were quite rigid. The muscles of the legs and arms were unaffected. The pulse was 130, the temperature was normal, and there was profuse perspiration. The hands and feet were very cold. Hot bottles were applied to the extremities and 30 grains of chloral hydrate were administered On the 15th at 10 A.M. the teeth could only just be separated, but the patient could still swallow without difficulty The pulse was 148 and the temperature was normal The abdominal muscles were very hard though there were no general spasms, the patient was much warmer but still he was perspiring profusely 10 cubic centimetres of antitoxin were injected. At 3 P M. the patient was very excited and for a short time before my arrival he had persistently refused to take food (previously he had been taking it well) The temperature was 101 8° F and the pulse was very rapid but of good volume. I now noticed for the first time momentary spasms of the opisthotonos variety of the muscles of the back and legs. The jaws were tightly clenched but owing to the irregularity of the line of the teeth food could still be easily administered by pouring the liquid within the inside of the cheek. The patient complained of a pain just below the heart which gradually increased in intensity The opisthotonos now gradually became more marked, though never of great severity, and the patient died quietly at 6 P M, apparently free from pain.

The antitoxin used was that supplied by the Pasteur Institute. Constipation was obstinate throughout, notwithstanding the administration of calomel and other aperient drugs

This case of acute tetanus appears to me to have the following points of interest 1. The antitoxin apparently had no effect whatever on the course of the disease 2. No premonitory symptoms were complained of before the onset of the disease on the eleventh day after the accident. 3 Although the pulse gradually increased in frequency the temperature was normal and it only rose to 101 8° F just before death. 4 The opisthotonos spasms were comparatively slight and unaccompanied by pain and were only noticed a few hours before death. 5 The end came quite quietly and painlessly and apparently was due to sudden heart failure. The patient was quite conscious to the end and was able to swallow his nourishment without much difficulty At the time of the accident the patient was in good health and had no history of previous illness

Salisbury

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON AN UNUSUAL FORM OF VESICAL CALCULUS

By HERBERT W PAGE, F R C S Eng,
SENIOR SURGEON TO ST MARY'S HOSPITAL, LONDON

BY suprapubic opening I removed from the bladder of an idiot boy admitted to hospital on Dec 9th, 1902, a calculus of such singular formation as to make it worthy of a short note in THE LANCET

The patient, aged seven years, was sent up from a village in Oxfordshire with the history of having begun in August last to show difficulty in passing his urine and to have abdominal pain. Not until three weeks before admission was a medical man consulted and by him he was sent to St Mary's Hospital. The child was then suffering agonies of pain which were most distressing to witness and at frequent intervals he was passing small quantities of alkaline urine containing pus and blood. Stone was suspected and Mr Nicholson, my house surgeon sounded but could feel nothing The bladder would not hold more than an ounce of fluid Nepenthe and fomentations were ordered, but there was next to no relief from pain On Dec. 11th I had the patient anæsthetised with a view to removal of the suspected stone by lateral lithotomy, but when I sounded I could feel none. I found it impossible to inject more than half an ounce of fluid into the bladder Now, however, there was to be felt a hard lump in the hypogastrium and as manipulation enabled me to pass the sound higher than before it was thought that the lump felt through the abdominal wall might be a calculus lodged in a bladder diverticulum near the fundus But the sound struck no hard substance. Lateral lithotomy was out of the question and accordingly I opened above the pubes and removed a calculus which Mr W H. Clayton Greene, the surgical registrar, has thus described "The mass was about the size of a large walnut and consisted of some 10 to 12 layers of laminated tough material in appearance like wash leather and like the decolourised blood clot from an aneurysmal sac The layers could be separated without difficulty In the centre of the mass was found a soft friable nucleus of mixed urates and phosphates about as large as a kidney bean This was doubtless the origin of the trouble and round it blood had been deposited in laminæ which had gradually been decolourised." No bladder pouch was discovered and it is not easy to account for the deposition of laminated blood clot round a nucleus subjected, as it must have been, to the perpetual wash of urine. I have never seen anything like it before. After the operation the child was kept in a warm bath and recovery was uninterrupted He very soon lost his pain and began to take as much interest in his surroundings as his idiot state would allow He was discharged well on Feb 10th.

THE MICROSCOPICAL OBSERVATION OF THE GLYCOGEN REACTION

By DR. G SPEZIA.

THE *microscopical reaction* with iodine showing the presence of glycogen in the white corpuscles may occur under both physiological and pathological conditions

Physiologically I have observed it in the human subject during the digestive leucocytosis following hearty meals Studying this phenomenon in guinea pigs which did not show this reaction in their blood I succeeded in producing it very distinctly, not only with injections of peptone into the peritoneal cavity as Gabrietschewsky did, but I obtained it even with subcutaneous injections of fats (olive oil), albuminoids (peptone), and carbohydrates (glucose) Physiologically, I have observed it also in pregnant guinea pigs. I therefore place on record this reaction with the formation of glycogen by the action of various diastases from various nutritive materials which exert a positive chemiotaxic action.

Pathologically, I have observed that it is always accompanied by hyperleucocytosis in excess of that which has long been known to occur in suppuration and that it is manifested in the polynuclear neutrophile cells, it is found in inflammatory foci and also in the blood In the blood it is the more evident in proportion to the closeness of the relations between the blood and the organs affected (as in croupous pneumonia, for instance)

The glycogenic reaction of the anæmias is found also in the hæmopoietic organs. This reaction is very evident in the sputa in inflammatory diseases of the lungs, in these cases I have observed it, not only in the white corpuscles, but also (and I believe that I was the first to do so) in the large phagocytes in which karyokinetic figures were displayed.

This reaction is the expression of a resistance of the organism to toxic agents, whatever be their origin, whether bacterial or not, a resistance which places in a circle (*il quale mette in circolo*) a substance (glycogen) which must serve to arouse an increased degree of defensive activity, as is proved by the following facts 1. This reaction is manifested after the injection of various nutritive substances. 2 In pathological cases it attains its highest point in the inflammatory centre, as, for instance, in the *foci* of pneumonia or broncho pneumonia, in which I have observed droplets of glycogen of a size from 0 5 μ to 20 μ (from 0 00002 to 0 0008 of an inch) 3. It is greater in severe toxic affections than in mild ones. 4 It is accompanied by hyperleucocytosis 5 It is accompanied by evidences of cellular division (for example, in tumours)

Turin.

NOTE ON A CASE OF HYDATID CYST OF THE SPLEEN

BY FRANK R. SEAGER, L.R.C P, L.R C S. EDIN, L.F P S GLASG,
HOUSE SURGEON SALOP INFIRMARY SHREWSBURY

A BOY, aged 11 years, was admitted into the Salop Infirmary on Jan. 11th, 1903, under the care of Mr A. Jackson, the senior surgeon complaining of "a lump in the stomach on the left side" The history of the case was that four months previously he had first noticed a swelling below the ribs on the left side. The size of this swelling was not at first definitely noticed and there was no pain, but it gradually increased and the lad began to experience slight pain which he likened to "stitch." It was now noticed that the swelling varied in size, being larger after a meal and at night. There was no sickness and the pain was not aggravated by taking food The bowels acted regularly The family history was very good. As regards the habits of the boy it was elicited that he was fond of accompanying keepers in beating for game and that he used to drink freely of the water in brooks and to eat watercress which was plentiful in his neighbourhood. Physically he was robust and well nourished. In the abdomen a swelling of the size of a small orange was distinctly noticeable in the left hypochondrium projecting from below the costal margin, with its centre just internal to the nipple line. Palpation of the tumour, beyond giving the sense of a cystic swelling, revealed nothing to suggest its nature or as to which was the organ affected The percussion note was resonant over the tumour There were no increase in splenic or renal dulness, no pain or tenderness on manipulation, and no appreciable movement with inspiration. The urine showed a trace of albumin. The diagnosis was thought to lie between a hydro-nephrosis or a hydatid cyst of some part.

Two days after admission an incision was made under an anæsthetic over the tumour and on opening the peritoneal cavity the spleen at once presented in the wound, with two-thirds of its anterior surface occupied by a tense shining, yellow coloured tumour which fluctuated on palpation. This was tapped and fully half a pint of clear limpid fluid was drawn off. The wound made by the tapping was then enlarged and a thick cyst-wall was shelled out in the ordinary way The wall of the cavity was then stitched to the skin, a tube was inserted, and the rest of the wound was stitched The boy made an uninterrupted recovery The cyst was single with no daughter cysts.

For permission to publish this note, which I hope may prove of interest from the diagnostic point of view, I am indebted to Mr Jackson.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON

The Excretion of Alkalies in certain Conditions of Renal Disease —Ehrlich's Dimethyl (p) Amido-benzaldehyde Reaction.—The Relation existing between Uric Acid Excretion and the Breaking Down of White Blood Corpuscles

A MEETING of this society was held on March 3rd, Dr W D HALLIBURTON the Vice-President, being in the chair

Dr W P HERRINGHAM read a paper on the Excretion of Sodium and Potassium in cases of Renal Disease. In experiments on the toxicity of urine when injected into the blood of animals, an account of which was given to the society three years ago, he had been led to disbelieve Bouchard's explanation and to conclude, with Feltz and Ritter Astachensky and others, that all the symptoms seen in rabbits might be accounted for by the potassium salts held in solution. There was no necessary connexion between the toxicity of urine and uræmia Indeed, it seemed to him probable that uræmia was not due to the retention of any normal product but to something abnormal. Nevertheless, he had thought it advisable to examine the excretion of sodium and potassium in renal disease to see if it varied from the standard of health. The standard of health was not, however very certain, it varied within considerable limits He had expected that if any marked change occurred in cases of nephritis it would be in the excretion of potassium. He found on the contrary, that the great variation was on the side of sodium. In patients who died there was found a great, in some cases a complete, retention of sodium He had made 16 analyses in 11 cases of chronic interstitial nephritis and of these six were fatal. In every one of them the sodium excretion was *nil* or very small. It was not so in any of the five cases which did not end fatally

He had made 20 analyses in nine cases of diffuse or parenchymatous nephritis and of these two were fatal Both showed complete absence of sodium from the urine on one or more days None of the seven cases in which recovery resulted exhibited this Thinking it might be due to diet or that the sodium might be passed in the fæces he had in one case of interstitial and in one case of parenchymatous nephritis analysed the diet, the urine, and the fæces for a series of days These were included in the numbers given above. A man aged 47 years, who died from chronic interstitial nephritis, with a dilated, hypertrophied, and fibrous heart, took during the last four days of life food containing 10 2 grammes of potassium and six grammes of sodium and excreted over 13 grammes of potassium but no sodium at all. A girl, aged 17 years, the subject of severe parenchymatous nephritis, took during eight days food containing 13 grammes of potassium and five grammes of sodium and excreted 13 grammes of potassium and 2 4 grammes of sodium (This close approximation of *ingesta* and *egesta* was considered accidental It was beyond what was possible in an investigation of this kind) On three of these days she excreted no sodium at all by the urine She did not die till 30 days after the end of the experiment. A man, aged 38 years convalescent from pleurisy, was used as a control In 11 days he took food containing 23 9 grammes of potassium and 9 3 grammes of sodium, and excreted in urine and fæces together 20 9 grammes of potassium and 10 1 grammes of sodium The sodium was wholly excreted by the urine, the fæces containing none. That the excretion of urea and salts was uneven in renal disease had already been shown by van Noorden and his pupils. The diseased kidney did not accommodate itself to change so quickly as the healthy, but that did not apply to those patients who had been on the same diet for a long time The results were very remarkable and if the absence of sodium was proved by further researches to be really an indication of fatal cases the analysis would be of importance in prognosis Retention of sodium was not, however, peculiar to Bright's disease. Salkowski had already shown it to occur in several acute fevers. Dr Herringham had also found it in two cases of large ascites repeatedly tapped In one of them there was no sign whatever of kidney disease, but the other was a doubtful case. The latter had left the hospital and could not be traced , the former was still an in patient. The retention could not be supposed to be due to inability of the kidneys to excrete sodium while excreting potassium freely It must be due, therefore, to some need of sodium within the organism. In the case of a large ascitic effusion yielding roughly 20 pints every fortnight of a fluid containing 0 3 per cent of sodium the need was obvious But this did not seem to apply to the cases of interstitial nephritis which had little œdema. Dr Herringham said that he owed special thanks to Dr Kennedy Orton and to Dr Hurtley, who had invented and elaborated the analytic process used, and to Dr Hurtley for his coöperation, without which the analyses, which were very long and laborious, could not have been performed. —Dr G O Garratt said that the retention of sodium in the body in the form of sodium chloride might be for osmotic purposes, or if not retained as sodium chloride the purpose could only be conjectured This retention of sodium chloride within the body had been observed by Prout in persons about to die and it had been found that after death from uræmia there was an excess of sodium chloride in the tissues. He suggested that the alteration in the osmotic tension of the blood in uræmia was in some way related to the retention of the sodium salts In fevers he had never found complete absence of sodium salts in the urine. If sodium citrate was given in fevers it was retained until the fall of temperature and presumably for the purpose of neutralising some acid condition He was of the opinion, however, that the sodium salts were retained in renal disease for osmotic purposes —Dr R. Hutchison referred to the retention of chlorides in pneumonia, which he said had been attributed to cloudy swelling of the renal epithelium which frequently accompanied that disease. He doubted the observation and had undertaken some investigations as to the excretions of chlorides in renal disease and in all the cases examined (which were not advanced cases of renal disease) he had always found a fair amount of chlorides. He considered that the absence of sodium salts in the urine of the cases cited by Dr Herringham was probably accounted for by the retention of the excess of serous fluid in the tissues owing to the imperfect secretion of water from the body which might be present in the later stages of renal disease.—Dr Herringham, in reply, said that the amount of chlorides generally varied directly with the sodium. The sodium was probably retained in the body as sodium chloride He agreed with the last speaker that the sodium chloride was probably retained within the body in the serum in the tissues.

Mr H. W Armit read a paper on Ehrlich's Dimethyl (p) Amido-benzaldehyde Reaction. He said that dimethyl (p) amido-benzaldehyde had the formula of $C_6H_4 - COH - N(CH_3)_2$ and was found by Ehrlich to unite with a constituent of normal and pathological urine, forming a red-coloured body The chemistry of this combination was not exactly known, but Ehrlich believed that the methylene group of the reagent joined with the unknown body in the urine, which he believed contained a pyrrol ring Proescher had studied the chemistry of the red compound and gave as its approximate empirical formula $C_{16}H_{24}O_6N_2$ which would give the formula of the unknown body as $C_7H_{15}O_6N$, after subtraction of O and addition of water After dealing with some points of the chemistry of the reagent Mr Armit pointed out that other observers had employed a somewhat inexact method of testing in the cold but he had come to the conclusion that the test could be more usefully applied by the following method. To one cubic centimetre of urine, heated to frothing, 0·01 cubic centimetre of an acid solution (2 per cent.) was added and if the urine was coloured cherry red the reaction was positive, while if the drop was seen to fall through the column of urine like a red worm, or when on the addition of more drops the froth was tinted, and the colour only appeared on the addition of two such drops he called it a colour change of the second degree, and when the colour appeared on the addition of the third drop a colour change of the third degree. Clemens had tested a number of pathological urines, but his results were irregular Koziczkowsky had used another method and had obtained results more like those which Mr Armit had obtained. Among his cases of gastro-enteric diseases he obtained good positive reactions in two out of eight cases of typhoid fever during the acute stage, while five gave less good reactions. None of the 35 cases convalescent from typhoid fever gave reactions Of three cases of acute appendicitis, one, which was complicated with fæcal fistula and pneumonia, gave a positive reaction and the other two gave no reaction, the abscess having been opened in both Of the cases of gastritis, only three gave second and third degree colour changes A number of other diseases were mentioned which gave no reactions In acute infective processes no reaction was obtained in rheumatic fever, rheumatic endocarditis, variola, or erythema nodosum , two cases of pneumonia gave positive reactions, while two gave colour changes of the third degree. In both the cases where a positive reaction was obtained the patients were very acutely ill One case of diphtheria during the acute stage gave a colour change of the second degree and was a moderately bad case, while two others which had been treated with antitoxin with apparent success gave no reaction Of six cases of scarlet fever during the acute stage two gave colour changes of the second degree, one a colour change of the third degree, and three no reaction. None of the convalescing patients (fever) gave a reaction. One case of vaccinia, which was admitted into hospital with the diagnosis of typhoid fever and in which the patient was acutely ill, gave a positive reaction 85 patients suffering from pulmonary tuberculosis were examined in this way 16 gave reaction up to the third degree and eight gave positive reaction, including one case of acute phthisis in whose sputum many cocci as well as tubercle bacilli were found A second case of acute phthisis, where tubercle bacilli were present in the sputum in almost pure culture, showed no reaction. No reaction was met with in miliary tuberculosis One case of bronchitis gave a change of colour, probably of the second degree , all the others gave no reaction. In influenza the antipyrin prescribed for the pains produced some colour changes. In infective endocarditis all the cases gave a positive reaction In early septicæmia and in the severer forms of sapræmia the reaction proved positive. In all he examined over 350 specimens of urine The diazo test did not correspond with this test Since all the patients who gave positive reactions were in fever and were sweating he sought to find out if sweating could produce it. Injecting pilocarpin nitrate into himself only increased the reaction slightly, as did hard exercise. Mr Armit came to the conclusion that the unknown body was either excreted in larger quantities or was manufactured in larger quantities under certain conditions of increased destructive metabolism, and he believed that the action of certain toxins especially some coccic toxins, produced it. From a clinical point of view he regarded the positive reaction as indicating a very grave prognosis and he pointed out that while a colour change of the second degree might assist to a correct diagnosis in some circumstances a positive reaction when there was clinical evidence of endocarditis pointed to the affection being infective The colour combination could be demonstrated in the tissues and he described some experiments on rabbits which showed that the unknown body was stored up in large quantities in the perichondrium and in smaller quantities in the white matter, kidney, liver, and mesentery in animals which had died from diphtheria toxæmia Papenheim suggested that the body was urobilin, but Mr Armit was able to disprove this. The urine of a horse suffering from tetanus gave the reaction well Horse's urine was supposed to be free from urobilin, and in this case Jaffé's and Gerhardt's tests were negative. The filtrate after precipitation with acetate of lead gave some colour change. Urobilin was increased in all cases of pyrexia, while the unknown body was not constantly increased. Several compounds were capable of joining dimethyl-amido benzaldehyde to form red colour bodies, but Mr Armit came to the conclusion that the pathological reaction was formed by the union of the reagent with only one body, the chemical nature of which was not known. It might contain either a pyrrol or a benzol ring — Dr A. E. GARROD criticised the correctness of the formula of urobilin given by Mr Armit.—Dr P HORTON SMITH asked whether the presence of the reaction in patients with chronic tuberculous disease was of grave prognostic significance — Mr ARMIT, in reply, said that the prognosis was bad in cases of chronic pulmonary tuberculosis in which the reaction was present.

Dr O K WILLIAMSON read a paper on the Relation existing between Uric Acid Excretion and the Breaking Down of the White Blood Corpuscles The conclusions arrived at by previous workers at this subject did not agree. Horbaczewski, however, demonstrated the relationship experimentally, whilst of the clinical observations those of Kühnau alone carried conviction. It was pointed out that isolated observations of uric acid excretion and of the white blood count at a corresponding time were of less value than continuous observations extending over a considerable period of time showing the corresponding variations. The observations recorded, therefore were carried out on the latter lines. The object aimed at was to determine whether an increased destruction of the white corpuscles as opposed to a diminished production was followed by an increase in the excretion of uric acid. This increased destruction would seem to be taking place, firstly, whenever a fall in the number of white corpuscles was followed by a rise in the amount of phosphoric acid excreted , secondly, a diminution in absolute number of the older forms of the white corpuscles, whilst the young cells did not correspondingly diminish would also point to an increase in destruction If, however, the young cells as distinguished from the older forms, diminished markedly in number this would indicate a diminished production. In order, then, to determine the times of increased destruction daily estimations of the amount of phosphoric acid in the urine were made and, corresponding to the daily white blood counts, differential counts from stained films. Eleven patients, most of them suffering from pulmonary tuberculosis, were chosen for the observations which were recorded in tables and curves. These showed (1) that in nearly every case in which a rise of the phosphoric acid curve followed a fall in the white corpuscle curve this rise corresponded with a rise in the uric acid curve , (2) that in the majority of cases confirmatory evidence of increased destruction could be obtained from a study of the differential counts , (3) that in those cases in which there were sudden and marked variations in the white corpuscle curve there were similar variations in the curves of uric and phosphoric acid , and (4) that in the case of the children the amounts of phosphoric acid and uric acid excreted were relatively greater than in the case of the adults and that the rises in the curves of phosphoric and uric acid followed more rapidly on the fall of the white corpuscle curve than in the case of the adults.—Dr HALLIBURTON said that he thought that it had been proved that uric acid originated from nuclein, either from the food or from the metabolism of the body He considered that undue stress was often laid upon the conditions of the leucocytes and investigators forgot the small volume occupied by the white corpuscles. If all the white blood corpuscles were destroyed every day the products of destruction would only form a very small quantity of the uric acid often excreted. The glandular cells of the liver, lymphatic gland, and other tissue contributed the larger share of the uric acid.—Dr W D'E EMERY suggested that the phosphorus resulting from the destruction of the white cells was often retained within the body and was not excreted.—Dr HUTCHISON asked if Dr WILLIAMSON had made any observations with regard to the condition of the uric acid secretion in cases in which there was a diminution of white corpuscles.—Dr WILLIAMSON replied.

CLINICAL SOCIETY OF LONDON

Exhibition of Cases

A MEETING of this society was held on Feb 27th, Mr HOWARD MARSH, the President, being in the chair

Mr LEONARD S. DUDGEON exhibited three cases of Volkmann's Contracture. The first case was that of a child, aged five years, who had fractured the right upper arm near the elbow joint in December, 1900 When put in plaster the fingers had become swollen and cyanosed and a pressure sore had formed on the flexor aspect of the forearm. In January, 1903, the forearm was found to be shortened and strongly pronated, the position of the hand and fingers being quite typical. Passive movement, massage, and faradism had resulted in very slight improvement The second case was that of a boy, aged nine years, who had met with an injury to the left forearm two and a half years before. A pressure sore had also resulted in this case In March, 1901, the patient was taken to St Thomas's Hospital and the electrical reactions showed partial reaction of degeneration. There was also partial motor and sensory paralysis in the region of the forearm. In February, 1902, Mr H. H. Clutton had performed resection of the radius and ulna. Under daily massage great improvement had taken place. The third case was that of a boy, aged eight years, who had injured the left forearm in December, 1901, after which the arm became shrunken, the fingers contracted, and there was sloughing on the forearm. In September, 1902, the child was taken to St. Thomas's Hospital, the hands and fingers then being in the typical position. In October Mr Clutton excised three quarters of an inch from the radius and ulna Great improvement had resulted.

Mr H B. ROBINSON showed a case of Dislocation of the Long Tendon of the Biceps Flexor Cubiti. The patient, who was aged 27 years, had had the head of the *left* humerus excised in St. Thomas's Hospital on Sept. 19th, 1900 by the late Mr William Anderson for recurrent dislocation Recurrence had occurred nine times in the preceding three years. The result had proved most satisfactory Six months previously he fractured the right clavicle which united rapidly On Jan 3rd last he fell from a van and subsequently noticed that the *right* arm could not be brought properly to the side The position of the arm was characteristic The humerus was abducted and inwardly rotated to a slight extent, the shoulder joint being then fixed attempted movement was attended by rotation of the scapula. The malposition could be easily rectified, after fixing the scapula, by bringing the elbow forward, thus relaxing the biceps, and then rotating outwards The condition was apparently associated with an abnormal laxity of the joint capsule and an increased play of the tendon in its groove —Mr A. PEARCE GOULD suggested that the abnormality might be due to a hypertrophied synovial fringe.—The PRESIDENT was not convinced that it was dislocation of the long tendon of the biceps. This displacement generally took place inwards and not outwards. The case, he urged, should be thoroughly investigated.—Mr ROBINSON, in reply, thought that the joint might be explored but asked what ought to be done if it proved to be a dislocation of the tendon He did not think that it was indispensable to remove the head of the bone as on the other side.

Mr T H KELLOCK showed a case of Varicose Internal Saphena Vein in a child, aged seven years. The condition was first noticed accidentally about a year ago The course of the vein seemed to be slightly abnormal, passing towards the inner surface of the thigh. Varicosity was also noticeable at the inner side and front of the patella, behind the internal malleolus, and over the inner side of the foot No cause could be discovered —Mr PEARCE GOULD said that he had never seen varicosity in so young a female patient, though varicocele was met with in male children. He thought that this condition supported the view that varicosity was not due solely, or even chiefly, to increase in venous pressure, but rather to over-development of the venous tissue akin to venous nævus —Mr HARRISON CRIPPS recalled the case of a girl, aged 15 years, who had enlargement of the whole limb, but in her case there was also involvement of the lymphatics. In Mr Kellock's case the limb was slightly longer and the foot was somewhat bigger than on the other side , in fact, the case resembled incipient giantism.—Mr KELLOCK, in reply, admitted that the limb was about a quarter of an inch longer than the other, but there was no indication of the lymphatics being involved He proposed to remove a piece of the vein

Dr H. D ROLLESTON and Dr W L. ASCHERSON exhibited a case of Acute Lymphatic Leukæmia. The patient was a female child, aged seven years, whose leading symptoms were debility, pallor, and shortness of breath There was a recent history of transient facial paralysis and lately her skin had bruised very readily A day or two before admission there had been pyrexia, epistaxis, and bleeding from the throat. When admitted there was still some bleeding from the gums and the tonsils, the glands were enlarged on both sides of the neck and in the left axilla, and the spleen extended to three inches below the costal margin. Examination of the blood showed 2,320,000 red corpuscles per cubic millimetre , there were some poikilocytosis and irregularity in the size of the individual corpuscles , the hæmoglobin amounted to 30 per cent , and the leucocytes numbered 60,000 per cubic millimetre, of which polymorphonuclear cells amounted to 3 3 per cent., hyaline leucocytes 1 8 per cent., and lymphocytes 95 per cent The lymphocytes were for the most part large and showed characteristic fraying of the edges and irregularity in shape —Dr J ROSE BRADFORD questioned whether the case was really acute and suggested that it might be a case of some standing in which the symptoms had suddenly become more prominent.—Dr ROLLESTON pointed out that the patient had markedly improved under treatment

Dr A. E RUSSELL exhibited a case of Syringomyelia with Dissociative Anæsthesia, Neurotrophic Joints, Muscular Atrophy, and Exaggerated Knee-jerks. The patient was a man, aged 50 years, with well marked atrophic arthropathy of the left wrist and carpal joints Both shoulders creaked on movement and the left had a tendency to swell on attempting to work The dissociative anæsthesia was distributed over both hands and arms, neck, scalp, and trunk down to the level of the fifth thoracic segment There was considerable muscular atrophy of some of the intrinsic muscles of the right hand, especially of the abductor indicis. The knee-jerks were greatly exaggerated but the gait was not spastic —Mr A. A BOWLBY recalled a case in which the patient complained of pain, &c., in the shoulder associated with characteristic destruction of bone, but this destruction was more apparent on the parts external to the joint He suggested the desirability of obtaining a radiogram of the joint.—Dr RUSSELL, in reply said that the rays showed considerable changes in the bones

Dr W PASTEUR exhibited a case of Cerebro spinal Meningitis with Optic Neuritis accompanied by complete loss of sight, followed by partial recovery of vision of an unusual character The patient was a woman, aged 22 years, in whom there was no evidence of syphilis. The present illness began in September, 1902, with severe occipital headache, pains in the arms and legs, vomiting strabismus, and sleeplessness On admission to hospital in October the leading symptoms were rigidity of the muscles of the neck, marked paresis of the arms and legs absence of knee-jerks, and Babinski's sign She began to improve after Oct. 22nd at which time the sight was totally lost and there was optic neuritis. The latter began to subside and vision was partially recovered on Nov 4th. In December she could not tell light from darkness but was able to distinguish a hand or a book. In January there was marked atrophy of both optic discs and she was still unable to see an electric light held close to her face, but she recognised the shapes of objects. In February she was recovering her vision for light and muscular power had been almost completely restored —Dr ROSE BRADFORD referred to a patient under the care of Mr John Tweedy who could not distinguish between light and darkness, though he could distinguish forms He thought that this curious condition had been described by certain German observers.

Mr RAYMOND JOHNSON showed a case of Webbed Arm in a lad, aged six years. The anterior fold of the right axilla was prolonged downwards in the form of a web which passed to the inner side of the elbow The pectoralis major was either absent or represented merely by a few fasciculi of the clavicular portion. In the free border of the web could be felt a slender fibrous cord, ending below at the internal condyle of the humerus and at its other extremity terminating in a muscular fasciculus attached apparently to the second costal cartilage (the chondro-epitrochlearis muscle). There was impaired development of the whole upper extremity and the four inner digits were webbed. The right scapula was smaller and lay at a higher level than the left.

Dr H BATTY SHAW exhibited two cases of Graves's Disease occurring in father and son The father, aged 46 years, had been suffering from weakness for the last four years. Exophthalmos of slight degree was noticed a little over two years before and a month or two later the neck was found to be swollen He was a very nervous subject and was frequently troubled with palpitation. There were also tachycardia, tremor of the hands, and retraction of the upper eyelids, and von Graefe's sign was well marked , flushing of the face was common and the skin generally was moist. The enlargement of the thyroid gland was greater on the right side than on the left. His son, aged 21 years, had always been rather nervous and there appeared to have been for several years some prominence of the eyeballs Nearly two years before he met with a rather severe bicycle accident and since then had noticed marked palpitation and he stated that the eyes had been more prominent since the accident. The pulse rate was about 120 to the minute, there was marked tremor of the hands, especially the right, and the eyes were prominent. There was also enlargement of the thyroid gland Albumin was present in the urine, sometimes only a trace, sometimes a well marked cloud.—Dr S P PHILLIPS said that he had met with the disease in mother and daughter He had seen the second of Dr. Shaw's cases previously, the chyluria having ceased in 1901.

Sir HUGH R BEEVOR exhibited Skiagrams of a case of Pneumothorax.

EPIDEMIOLOGICAL SOCIETY

Risk of Introduction of Yellow Fever into Asia

A MEETING of this society was held on Feb 25th, Mr SHIRLEY F MURPHY being in the chair

Dr PATRICK MANSON, F R S , read a paper on the Panama Canal and the Risk of the Introduction of Yellow Fever into Asia. The diffusion of disease by insects and especially by mosquitoes as intermediary hosts of the specific hæmatozoa was, he said, a subject presenting problems of surpassing interest and the recent inclusion among those thus propagated of yellow fever, the scourge of tropical America, the etiology of which had hitherto baffled investigation, was full of promise, giving a far less hopeless aspect to the question of its prevention He would confine his remarks to (1) the risk of the extension of the fever to the populous regions of Asia involved in the opening of the Panama Canal to which the Government of the United States was pledged , and (2) the means to be adopted for lessening the risk. Shiploads of labourers from China, Japan, and India would soon be plying between Panama and the sea ports of Asia, and if the traffic were unrestricted the disease would inevitably be introduced into the populous, densely crowded, and insanitary cities of China and India, where its ravages would be incomparably greater than they could be in the sparsely peopled countries and smaller cities of South America. The Epidemiological Society had a duty and an opportunity that it could not ignore to impress on the Governments of the civilised world the urgency of the occasion The freedom from yellow fever hitherto enjoyed by Asia was, like that of America until recently from cholera and the plague due, not to any conditions unfavourable to its spread, but to the absence of direct communication with the localities where it was endemic, California and Chili lying beyond the fever zone on either side of the equator It was true that the parasite was present in the blood for a few days only at the commencement of the fever, but if taken from the patient during this period by a mosquito it retained its vitality in the body of the insect for eight or ten weeks and might be at any time communicated by its bite to previously healthy individuals. The yellow fever patient was in himself no more dangerous to others than was the sufferer from malaria and it was the stegomyia that, like the anopheles, conveyed the germs from him to others, infecting them in turn. It was thus quite possible for a ship, the crew of which were perfectly healthy not only on sailing but throughout the voyage, to convey the disease provided the passage did not exceed, say, ten weeks Stegomyiæ that had recently bitten a fever patient got on board in the harbour and might or might not attack the crew, when the vessel put to sea they sought shelter in the hold and if sugar, fruit, or other food or rats were accessible probably did not leave their hiding places until disturbed by the discharge of the cargo at the port of arrival, when the infected insects attacked those who whether members of the crew or labourers belonging to the port, were engaged in the work of unloading Cases might or might not occur during the voyage, but it was not they but the infected stegomyiæ that would introduce the disease into the new locality In one or other way yellow fever had been carried to every seaport on the eastern coast of America between lat. 38° N and 38° S., as well as to Peru on the west coast In Africa it was still limited to the west coast, north of the equator, and in Europe, though it had never become endemic, the footing it temporarily obtained at Lisbon in 1853 proved that such a contingency was not impossible. The stegomyia fasciata was the most widespread, but other species could serve equally well as hosts, so that no country in the tropical or warmer temperate zones was safe Such being the etiology of yellow fever it was evident that it could not be carried by cargo or fomites, nor even by infected persons, to places where stegomyiæ were absent. Quarantine and disinfection of cargo were alike useless, the sole means of prevention being the extermination of the stegomyiæ, for which, so far as shipping was concerned, sulphur fumigations of the hold and between decks were the most efficient, with the destruction of the larvæ in the bilges and water tanks On land the war must be conducted on the same lines as had been employed against the anopheles. That this was feasible had been amply proved by the Governor General Wood, himself a medical man, and Dr Gorgas at Havana There the deaths for the past ten years had averaged 467 per annum but between April, 1901, and March, 1902, there had been only five deaths and since that time there had not been one. He trusted that the Americans, though they had no direct interests in Asia, would carry out the sanitary control of the canal with equal thoroughness, but it would be advisable that the civilised powers most concerned, such as England, France, Germany Holland, Italy, Japan, and Siam, should constitute an international board of supervision and subvention. The measures he would recommend were simple enough but must be inexorably enforced. Every vessel coming from, or having called at, a port within the yellow fever zone should be boarded on entering the eastern end of the canal by an officer and assistants whose duty would be to destroy by fumigation and other means all stegomyiæ on board and before leaving the canal it should be inspected by others who should satisfy themselves of the completeness of the work. To prevent the infection of a vessel in its passage through the canal the country for half a mile on either side should be cleared of trees, standing water, and everything that could afford shelter for mosquitoes or their larvæ. Dr Manson remarked that all that was known of the etiology of yellow fever was due to the labours of a band of American epidemiologists, Major Walter Reed, Dr Carroll, Dr Lazear Dr Agramonte, and Dr Guiteras, the pioneer being Major Reed who though he never saw the hæmatozoon itself, having satisfied himself of its transmission by the stegomyia, applied this knowledge with the brilliant results that had been obtained at Havana. Major Reed and Dr Lazear however, died martyrs to their work

Dr NUTHALL remarked that the extinction of yellow fever in Havana had removed a great danger from the United States since in every epidemic in Florida and the valley of the Mississippi the disease had been introduced from that port. The mosquitoes stegomyia fasciata or other species, were very retentive of vitality so long as they had access to water, as in the holds of vessels in the water tanks of which the larvæ might be seen in thousands. It was as insecticides, not as germicides that sulphur fumigations had been found successful. He might mention that one epidemic in New Orleans had cost the city 10 000 000 dollars in various ways

Dr STRONG stated that yellow fever had recently been very prevalent in Panama and was constantly carried from one port to another on the esat coast of South America. He described at some length the several importations into western and southern Europe and said that at least six instances had been recorded recently of its conveyance by ships on which no cases had occurred. The distance between Panama and Honolulu was less than that between Rio de Janeiro and Naples.

Dr BOUSFIELD, who had been through several outbreaks in the West Indies, complained of the apathy of the British authorities even when convinced of the truth of his representations. The only preventive work in respect of malaria—that at Sierra Leone—was due to private enterprise, the colonial governments would do nothing

Dr LOUIS SAMBON insisted on the necessity for immediate action, the danger being more imminent than Dr Manson represented, since a steam service would very shortly be opened between China and Mexico, and should the disease once be introduced into China it would rapidly spread to Japan, India, and Australia The prophylaxis was simple, but the difficulties presented by popular ignorance and official apathy were well nigh insuperable.

LIVERPOOL MEDICAL INSTITUTION

Human and Bovine Tuberculosis

A MEETING of this society was held on Feb 26th, Mr RUSHTON PARKER, the President, being in the chair

Dr NATHAN RAW read a paper upon Human and Bovine Tuberculosis. He commenced by saying that Professor Koch, the greatest authority upon tuberculosis, in an address at the British Congress on Tuberculosis in London in 1901 greatly disturbed the scientific world by announcing his now well known theory that human and bovine tuberculosis were separate and distinct diseases and that bovine tuberculosis could not be conveyed to man. Now, it must be admitted that the great body of experimental evidence was in favour of Koch s first contention that the two diseases were distinct. Phthisis pulmonalis was essentially a disease of young adult life. It was rare to see it as a primary affection under the age of 12 years, the great majority of deaths taking place between the ages of 30 and 40 years as his tables would show On the other hand, strumous or tuberculous joints, enlarged joints, spinal disease, and abdominal tuberculosis with tabes mesenterica were essentially diseases of infancy and childhood and were only rarely seen in adult life. From these general clinical and pathological observations Dr Raw inclined to the opinion that primary intestinal tuberculosis, tabes mesenterica, and other tuberculous affections of the serous membranes in children were probably bovine tuberculosis conveyed by milk and were not in any way related to human tuberculosis, although the bacillus of Koch was found in them all and was identical. Veterinary authorities, such as Nocard Bang Dollar and McFadyean, agreed that about 30 per cent. of dairy cattle suffered from tuberculosis Dr Raw wished to point out that the infection commenced in the mesenteric glands from the intestine, slowly spread to the retro-peritoneal glands then through the diaphragm to the glands in the posterior mediastinum and finally to the lungs. If the child lived long enough the brain might be affected too At necropsies this process had been corroborated again and again Dr Raw remarked that taking all these facts into consideration and after a careful study of tuberculosis in all its forms during the last ten years, he was of opinion that bovine tuberculosis was very virulent for children and was accountable for tabes mesenterica and other varieties of abdominal tuberculosis—in fact, that it was more virulent to children than was human tuberculosis There was much evidence, also, that acute miliary tuberculosis, especially that of the typhoid form, was in reality a bovine tuberculosis produced by ingestion of food. Since the two diseases could not exist together in cattle, might it not be that they could not exist together in man ? and that the serum of a cow affected with tuberculosis might have a curative effect in a case of pulmonary phthisis exactly on the same lines as small pox and cow-pox ? Who knew ?—it was only an idea, but in the treatment of such a fell disease anything was worth consideration It would appear, therefore, that infants and young children with a feeble power of resistance were susceptible to bovine tuberculosis more especially if they were fed for a prolonged period on infected milk, but that as age advanced the susceptibility decreased, until at adult life there was little risk of more than a purely local affection of the glands of the neck, which, however, might occasionally extend directly to the lung, and even result in a general miliary tuberculosis Considering that tuberculosis was so common, and even increasing, in this country among dairy cows, something ought to be done by the legislature to prevent the wholesale distribution of tuberculous milk to the public A more rigorous inspection of dairy cattle should be made by the health authorities and as it was perfectly easy and certain by the tuberculin test to diagnose a tuberculous cow there should be no difficulty in at least eradicating the disease from dairy cattle. The onus of responsibility of supplying pure milk to the public should not rest on the health authority but on the producer, and although the health authority could do a splendid and humane work by providing the community with sterilised milk at a cheap rate, still the real responsibility must be with the man who actually delivered milk for sale to the public Dr Raw concluded by expressing the opinion, based almost exclusively upon clinical and pathological evidence, that human and bovine tuberculosis were separate and distinct diseases, as shown by Professor Koch, but that the human body was susceptible to both, and especially to bovine tuberculosis in the early periods of life. The two diseases were so rarely seen together in the human body that there seemed to be some ground for presuming that they were antagonistic to each other and that bovine tuberculosis might possibly confer an immunity against human tuberculosis. If this opinion should prove correct he ventured to submit that it would entirely reconcile the conflicting opinions which had been so frequently expressed during the last two years on that most terrible of all diseases.

The PRESIDENT said that opinions formed upon a question of this kind were based partly upon clinical impressions and partly upon scientific considerations. He thought that they were in need of pure science to control the impressions which they were tempted to rely upon. He had himself not gone much into the intimate pathology of the question He had originally operated for the purpose of removing the local disease An experience of 30 years had satisfied him as to the correctness of this procedure, he had only met with phthisis pulmonalis four times out of about 300 patients

Dr W CARTER recognised the ingenuity of Dr Raw's suggestion of two different diseases but he considered that the view that true human tuberculosis could not be communicated by bovine tuberculosis was too absolute and was disproved by recorded facts. If the words had been "is not generally communicated" he, like everyone else, must have assented It was too early to dogmatise He thought that the difference of results probably depended on difference of soil, the seeds being identical.

Dr R CATON admitted that apparently two forms or types of tuberculosis occurred in the human subject (1) pulmonary phthisis, and (2) tubercle of glands, bones, and nervous organs, and that usually the course and termination of the two types presented marked differences This fact supported Dr Raw's interesting generalisation Dr Raw's theory, if fully demonstrated, would have most important practical results

Dr W ALEXANDER said that he had had 62 cases in the last three years and out of 885 babies in the Liverpool workhouse hospital 82 were diagnosed as suffering from marasmus or tabes mesenterica. A good many cases of tabes mesenterica recovered completely, so that it was probable that in many cases the disease was not tuberculous. The children who suffered from this disease belonged to the lowest class of society They lived on small quantities of milk which was used without being sterilised Many of them suffered from attacks of intestinal and gastric catarrh through improper quantity or quality of food and these attacks produced enlargement of the glands in just the same way as eruptions of the scalp and discharge from the ear produced enlarged glands in the neck. If the intestinal condition recovered the glands lessened in size, but if the condition was prolonged for a sufficient time the microbe of tubercle gained admittance and they had tuberculous disease just as happened in the neck or glands elsewhere If Dr Raw's views were correct they would have to go back to the sterilisation of milk Dr Alexander hoped that the whole subject would be promptly investigated

Dr A S F GRÜNBAUM agreed with Dr Raw that tabes mesenterica was due in many cases to milk carrying bovine tubercle bacilli. Experiments on anthropoid apes tended to confirm this view Dr Raw's isolation of the bovine bacillus from a mesenteric gland was the first published confirmation of Ravenel's results in the same direction But that was no reason for considering the diseases produced separate and distinct. It seemed probable that the disease was one and the same Whatever the source of the bacillus although undoubtedly more virulent when of bovine origin, the lesions produced by the inoculation of either form were practically the same.

Sir W M. BANKS said that if Dr Raw's thesis were true then persons dying from phthisis need not specially show any signs of having been afflicted during childhood in any marked degree with tabes mesenterica, diseased cervical glands, or articular trouble It was his conviction that children who suffered from glandular and articular diseases did not suffer in later life in any marked degree from phthisis. He therefore was opposed to the dissections of the neck sometimes practised These children died from exhaustion and waxy disease when they did succumb For himself he found a difficulty in looking upon bovine and human tuberculosis as two absolutely distinct diseases. He would prefer to call them variants of the same disease affecting each its own locality The seeds of the various kinds of cabbage did not show notable differences of appearance, but the wild progenitors of the edible flourished in the sea while the big cultivated cabbage would only grow on good land. Soil in this question probably had much to be reckoned with.

Dr J HILL ABRAM said he had never been convinced of the soundness of Koch's theory He would like to draw attention to the following point Koch's great dividing characteristic between bovine and human tubercle was the non communicability of the two organisms to human and bovine respectively—i.e, human to cow and bovine to man. Ravenel's, and now Dr Raw's cases shattered Koch's theory and restored the unity of tubercle

Other speakers followed and Dr RAW replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Feb 17th, Dr H J Campbell, the President, being in the chair —Dr F W Eurich brought forward a communication upon the Treatment of Epilepsy, chiefly with reference to the theory that there is in epilepsy an excessive storage of sodium chloride in the body He detailed a number of cases which had been very successfully treated by comparative privation of salt and its replacement as an article of diet by sodium bromide, about half an ounce of which was taken each week. In one case intermission of the fits had been procured, when the patient began to take salt again freely The fits at once recommenced but were stopped again when the ingestion of salt was discontinued. Trinitrin in occasional doses was useful in relieving headache.—The President, Dr A H. Robinson, Mr S W Rhodes, Dr A. H. Bampton, and Dr J Metcalfe took part in the discussion.—Dr R. A R. Lankester read a paper on the Administration of Anæsthetics with some remarks on Somnoform. Ether, he said, was undoubtedly safer than chloroform and ought to be used in all cases where it was available. The preliminary administration of nitrous oxide was strongly advocated in ether cases, as being more pleasant, quicker, and safer for the patient In prolonged operations the sequence of nitrous oxide, ether, and chloroform was advocated, the change to chloroform not to be made during struggling or during deep ether anæsthesia. Ether was quite suitable for children six years of age and upwards If nitrous oxide was not available as a prelude to ether a few whiffs of chloroform or mixture of ether and chloroform might be given till the patient was partly unconscious. Oxygen might be an important adjuvant to ether in cases of spasm such as might occur in alcoholic or asthmatic patients. Mixtures of ether and chloroform were of value in old persons, very fat subjects, and those with severe emphysema and bronchitis. These mixtures were wasteful and had many of the dangers of chloroform. Chloroform ought to be given without closed apparatus of any kind, so that there might be no doubt about the admission of plenty of air Somnoform, he said, was a mixture of 60 parts of ethyl chloride, 35 parts of methyl chloride, and five parts of ethyl bromide The components had been arrived at by physiological experiments. The advantages claimed for it were (1) that no cumbersome apparatus was required, (2) that its action was very rapid, (3) that the return to consciousness was rapid, and (4) that it was very safe. It was administered by spraying it into a mask which fitted closely on the face. The patient's colour remained good, the respirations were regular and deep, and became sonorous when anæsthesia was induced. The pulse was slightly quickened and the tension was increased There was slight rigidity which passed off as the anæsthetic was pushed, the conjunctival reflex was lost, and the pupils became dilated and fixed. When this point was reached the mask was removed as the patient was fully "under" The period of anæsthesia was quite one and a half minutes. Somnoform was available for cases requiring a rather longer period of anæsthesia than could be obtained by nitrous oxide and where otherwise chloroform or ether would be used. The patient was generally able to walk away a few minutes after the administration There was not as a rule any vomiting —Dr J G Moffat showed the pieces of a Uric Acid Calculus weighing seven and a half ounces which had been removed from the bladder through the perineum after lithotrity had been performed —Dr William Craig showed Fœtal Bones extruded from an abdominal abscess 18 months after probable rupture of an ectopic gestation.—Other specimens were shown by Mr C F M. Althorp, Dr R. H. Crowley, Dr T J Wood, and Mr F E. Meade.

North of England Obstetrical and Gynæcological Society —A meeting of this society was held in Liverpool on Feb 20th, Dr J E. Gemmell, the President, being in the chair —Dr W E. Fothergill (Manchester) showed a specimen of Hyperplasia of the Thyroid Gland from a Fœtus in a case of Eclampsia.—Professor A. M Paterson showed a Uterus having a Utero-Vaginal Septum —Dr D Lloyd Roberts (Manchester) showed an Ovarian Tumour which with its contents weighed 30 pounds. It was removed from a woman, aged 60 years and contained 16 pints of brownish, grumous fluid.—Dr Fothergill recorded a case of Hyperpyrexia associated with Thrombosis of the Vena Cava Inferior The patient was delivered by a midwife on March 21st 1902. Fever set in and became intensified until the patient's removal to hospital on the fifth day Improvement followed intra uterine douching at first, but a relapse occurred on the 31st, so the uterus was curetted, several pieces of placenta being removed On April 6th the temperature reached 111 2° F but was reduced to 107° by hot sponging Thrombosis of the right femoral vein was quickly followed by involvement of the left and from this time onwards till the patient's death on May 14th there were no special symptoms except increasing weakness, though the temperature continued high and remittent, with repeated rigors. There was no sign of suppuration or embolus in any other organ. The immediate cause of death was œdema of the lungs The necropsy showed that the uterus and other pelvic organs were normal, there was no sign of general or pelvic peritonitis, the inferior vena cava and its tributaries were filled with ante-mortem clot from the heart downwards. He was inclined to regard the curetting as the cause of the thrombosis.—Dr A. C F Rabagliati (Bradford) referred to cases in which temperatures of as much as 120° had been recorded and held that mere elevation was not so important as variability of temperature He suggested that the thrombosis might have been due to some general condition—e g, hyperinosis of the blood.—Dr J B. Hellier (Leeds) read notes of a case of Double Pregnancy in a Double Uterus. The patient, aged 34 years, had had three normal labours previously During the fourth pregnancy the uterus was larger than usual. After a normal labour a female child was born, head first, the placenta following The presence of a second child was discovered, but the medical attendant on introducing his hand found the uterus empty Dr Hellier found a second os lying high up in front of and to the left of, the other, and delivered a male child by podalic version. The uterus was bicornate, a fairly thick septum dividing the two cavities, and there were two separate ora uteri opening into a single vagina.—Dr H. Briggs said that he had seen three cases of the kind and he confirmed Dr Hellier's account of the relative positions of the two ora uteri.—Dr T Arthur Helme (Manchester) read a short communication on Dilatation of the Cervix Uteri in Eclampsia of Pregnancy by means of Bossi's dilator Dr Helme found that this dilator could effect full dilatation in 20 minutes, another ten minutes being required for complete delivery with forceps. He had been surprised by the ease and comfort with which the instrument could be used without any laceration of the cervix and thought this means afforded a marked contrast with manual dilatation and its frequently accompanying discomfort and cramp.—Mr S. Rumboll (Leeds) said that he had used Bossi's dilator in a case at the sixth month and he preferred it to fingers and Barnes's bags It was easily used and did not tear the cervix.—Dr A. Stookes and Dr Glynn Whittle also took part in the discussion

Glasgow Obstetrical and Gynæcological Society —A meeting of this society was held on Feb. 25th, Dr J Nigel Stark, the President, being in the chair —Dr. J K. Kelly opened a discussion on the Diagnosis and Treatment of Suppurative Conditions in the Pelvis He divided the cases into two groups according to their situation, the first was invasion of the connective tissue, the second of a closed cavity either natural or acquired. With regard to division of the cases according to the etiology, those occurring in the puerperium were usually from infection of the cellular tissue, while in the non pregnant cases the preformed cavities were usually involved. There were exceptions, of course, to the rule. The reason for this selection of tissue was obvious. During delivery traumatisms were frequent and injured tissue was easily infected. The cervix being the most commonly injured the course of the infection was through it to the pelvic cellular tissue The infection after invading the broad ligaments, usually passed forwards and became subcutaneous above Poupart's ligament. Occasionally however, the route took a posterior turn and the track extended upwards as far as the kidney, the abscess might point in the loin or even burst into the pleura. It was fortunate that these collections tended to open externally In the non pregnant cases the track taken by the infection was along the mucous surface. After a chronic endometritis the tube was apt to become implicated and when this took place the abdominal ostium became closed and pus collected in the tube. The ovary when it became the seat of the disease formed either a large pus cavity or a number of smaller ones Further extension of this infection involved the bowel and the peritoneum, &c. The progress of the malady was according to the situation. When the cellular tissue was involved the infection worked its way to the surface while when in a closed cavity its progress was more difficult. Thus in long standing cases the virulence of the infection became less and might disappear altogether With regard to the differential diagnosis the history, location, and course were all different in the two types In cellular abscess there were parturition and injury, in pyosalpinx there was no injury save gonorrhœa, long standing endometritis, or the fact of intra uterine medication having been resorted to The treatment of the condition was relative to its nature. When the connective tissue contained pus it ought to be evacuated. Sometimes there were large effusions which did not progress to the formation of pus and it was difficult to say if pus were really present. Many different phases of the disease were to be considered. In certain cases it might be expected that the trouble might subside, while a tubal disease giving rise to attacks of peritonitis, to adhesions, and tending to wear out the patient from the pain, was a condition definitely requiring operation.

Forfarshire Medical Association —A meeting of this society was held on Feb 14th, Dr. A. J Duncan being in the chair —The Secretary showed, for Mr. D M. Greig, a Boy after treatment for severe injuries to the right upper extremity These injuries were a severe compound fracture of the humerus (a considerable part of the bone was denuded of periosteum) and a simple fracture of both bones of the forearm in its upper half. A large part of the humerus necrosed and the sequestrum was removed. The result showed a very useful arm with free movement at the elbow —Mr G Halley read notes of eight cases of Hereditary Ichthyosis of the Palms of the Hands and Soles of the Feet and showed a table drawn up with six other cases affected in five generations, making 14 cases in all. The table, like other tables published of similar cases in four or five generations, showed that both sexes were alike affected and that the affection passed through males and females alike. He was of opinion, from what he knew of this family, that the affection in such cases appeared soon after birth and if looked for at birth would probably be noticed then. All of the patients had good health and were able to earn a livelihood in the mills —Dr J M. H. Macleod read a paper on the Treatment of Skin Disease by the Finsen Light and the X Rays. He considered that in suitable cases of lupus the treatment by the Finsen lamp was the best. Coarse skins required longer treatment than fine skins and dark complexions required longer treatment than light complexions. Too early exposure after reaction or too long exposure was dangerous. Epithelioma was sometimes set up Out of 70 cases treated by him 11 were cured apparently and one was made worse. He had found this treatment beneficial in gummata and granulomatous patches occurring in sycosis of the chin. In some forms of lupus erythematosus it was harmful. Comparing the Roentgen rays with the Finsen rays he said that the Roentgen rays were more powerful, more difficult to regulate, and had a totally different action, they also had a wider field of action and therefore protective coverings beyond the field required were a necessity Dermatitis following exposure to x rays had been succeeded by epithelioma. Treatment by x rays required careful watching It was an excellent adjunct to treatment by Finsen rays but not equivalent. It was useful in some cases of ringworm of the scalp and favus but not in hypertrichosis Its chief value was in rodent ulcer and in superficial epitheliomata —Professor D MacEwan, Dr R. Sinclair Mr Halley, and Professor J A. C Kynoch took part in the discussion.

Therapeutical Society —A meeting of this society was held on Feb 17th, Mr W Parson, Master of the Apothecaries' Company, being in the chair —The Secretary read a brief sketch of the formation of the society, which was started in July last. The Apothecaries' Company agreed to give the use of its rooms free of charge. Rules were drawn up and officers and council were chosen. 107 Fellows joined the society —Dr R. Hutchison read a paper on the Use of Acid Sodium Phosphate in Alkalinity of the Urine. The alkalinity of the urine was estimated either by precipitating alkaline phosphate by barium chloride and then estimating the acid phosphates by adding uranic nitrate solution or by adding phenalphthalein and titrating with a standard solution of alkali He found that mineral acids, even in large doses, had very little effect in rendering the urine acid, nor did organic acids have more than a slight effect, but the acid sodium phosphate had a marked influence on the reaction It had been tried with very satisfactory results in cases of cystitis and it was found particularly useful after operations on the bladder to keep the urine acid. The dose was from 30 to 60 grains every three hours, but it was best given by dissolving two drachms in a pint of water and allowing the patient to drink it from time to time If diarrhœa was produced the drug should be stopped for a short time.—Dr James Burnet read a paper on Ichthyol in the Treatment of Pulmonary Disease. He said that ichthyol was a definite chemical compound and formed a thick liquid substance of dark brown colour with characteristic taste and odour It contained from 15 to 16 per cent. of sulphur At present it was much used as an external medicament but its internal use had been much neglected in this country It was certainly of great service in cases of pulmonary disease. It arrested the disease when administered in suitable cases, but did not eradicate it Good results were also obtained in cases of bronchiectasis The mode of administration was by means of capsules, the dose varying from eight to 20 grains four times a day In pulmonary tuberculosis it was to be preferred to creasote and its preparations, for ichthyol never caused any gastric derangement, whereas creasote often did. To be of any service ichthyol must be used for a long period.

Midland Medical Society —A meeting of this society was held in Birmingham on Feb 4th, Dr H. W Langley Browne, the President being in the chair —Mr W Edward Bennett showed a specimen of Perforated Typhoid Ulcer which had been operated upon by him The patient, a married woman, 23 years of age, was admitted into the workhouse infirmary on August 12th 1902, being then in the second week of the disease, which presented the usual symptoms She progressed favourably until Sept. 8th, when a relapse occurred, the symptoms indicating perforation. On the 10th some 14 hours after perforation was supposed to have occurred the abdomen was opened and a perforation of about the size of a small pea and situated about four inches from the ileo-cæcal valve was found and stitched up The patient progressed very favourably until the fifth day after the operation when a severe hæmorrhage from the bowel resulted in her death. At the necropsy two other large ulcers were found in the ileum below the seat of perforation, one of which had apparently eroded a large vessel in its immediate neighbourhood. There was no peritonitis.—Mr Bennett also showed a specimen of Gastric Ulcer taken from a female, aged 18 years, who had suffered from anæmia and symptoms of gastric ulcer, dating back for 12 weeks Symptoms of perforation showed themselves suddenly on the morning of Jan. 4th, 1903, and on opening her abdomen 16 hours afterwards Mr Bennett found gastric contents in the peritoneal cavity and a slit-like perforation at the pyloric end of the stomach just below the junction of the gastro-hepatic omentum and the lesser curvature of the organ. The perforation was stitched up and an opening was made above the pubes The abdomen was irrigated and a tube was left in the pouch of Douglas The patient died at 8 A.M on the 5th At the necropsy a large ulcer was found on the posterior wall and lesser curvature of the stomach, the perforation having occurred at its upper and anterior margin. There was general peritonitis —Dr O A. Leedham Green showed a patient from whom he had removed the Gasserian Ganglion by a modification of Krause's method —Mr J Jameson Evans read a paper on the Occurrence of Neuroretinitis in Anæmia.

Dermatological Society of Great Britain and Ireland —A meeting of this society was held on Feb 25th, Dr J H. Stowers, the President, being in the chair — Dr T D Savill showed a case of (?) Tinea Imbricata with a microscopical section of the affected skin Dr Savill and Mr A. Shillitoe exhibited photographs of typical cases of the disease.—Dr P S Abraham showed (1) a case presenting a Vesiculo-varioliform Eruption with tendency to leave punctate scars (the disease was of 12 years' duration and was contracted in South Africa), (2) a case of Ichthyosis in a baby, (3) a case of Lupus Erythematosus, and (4) a case of Tinea of the Scalp in an elderly woman (some hairs from this case were placed under the microscope) —Dr E G Graham Little showed (1) a case of (?) Pemphigus Foliaceus, (2) a Perforating Ulcer of the Foot in a man who showed no signs of Locomotor Ataxia, (3) a case of Urticaria Papulosa presenting a nearly universal eruption of flat shining papules of 14 days' duration (lichen planus infantum), and (4) a man suffering from Seborrhœa, with Alopecia of the Scalp and a Ringed Eruption on the Limbs —Mr Shillitoe showed —1 A case diagnosed as Tertiary Roseola. The man contracted syphilis six years previously and was fully treated for the same In September, 1902, he developed small sores on the penis, which had constantly recurred since and were still present in the form of herpetic blisters and small round abrasions The roseola appeared in November (It was considered by some members that this was a case of re-infection) 2. A case presenting Syphilomata of the Tongue and Lip 3. A case of Recent Syphilis in which the eruption on the neck tended to form very distinct hollow squares —Dr A. Eddowes showed a case of "Vest Rash" and a section of a Sebaceous Cyst taken from the patient.

Edinburgh Royal Medical Society —A meeting of this society was held on Feb 27th, Dr W H. Prentice being in the chair —Dr A. H. Firth read notes on a case of Ophthalmoplegia. The patient was a woman, 34 years of age, and the condition was brought on by a severe chill On the right side there were ptosis, complete immobility of the eyeball, and loss of pupil reaction to light and accommodation. Under iodide of potassium and counter irritation the symptoms improved.—Dr W B Drummond gave a lantern demonstration on several surgical affections of children. He showed skiagrams of tuberculous and syphilitic diseases of bones, osteomyelitis, fractures and dislocations and congenital dislocation of the hip —Dr S A. K. Wilson read a dissertation on Pigmentation

Royal Devon and Exeter Hospital —The annual meeting of the subscribers to this institution was held on Feb 26th, under the presidency of the Bishop of Marlborough. The medical report stated that during 1902 the in-patients numbered 1349 as compared with 1258 in 1901 and that 5214 out-patients were treated against 5103 in the previous year The financial statement showed that the income amounted to £7141 and the expenditure to £9616 To make good the deficit the committee had been obliged to withdraw some invested funds The Bishop of Marlborough was re-elected president

Reviews and Notices of Books.

International Clinics Vol. II. Twelfth Series. Edited by HENRY W CATTELL, A.M. M.D London J B. Lippincott Co. 1902. Pp 295. Price 10s 6d

THIS volume of International Clinics, which is the second of the twelfth series, contains a number of papers of very unequal merit. Although nominally international the character of this particular volume is clearly transatlantic and, although comparisons are not always the best means of description, it may perhaps be permitted us to contrast this hospitable receptacle for literary productions with the somewhat similar and decidedly superior publications of our own Sydenham Society Among the contributions which deserve special mention must be included that of Dr R Romme (Paris) which supplies a full account of Gersuny's method of prothesis by subcutaneous injection of vaseline. The reported successes of this new development of plastic surgery were at first regarded as the vain boastings of megalomania. At the present time, however, as may be gathered from the perusal of Dr Romme's paper and from recent cases published in THE LANCET the record of experimental and clinical work clearly demonstrates that the method deserves a place amongst the most useful innovations in surgery Dr Romme's paper, though containing much useful and practical information, is of the nature of special pleading rather than of a critical review Another article which will be read with interest is from the pen of Professor Thomas Jonnesco (Bucharest). This paper describes the successful treatment of exophthalmic goitre by the heroic method of resection of the cervical sympathetic, his heroism has in a certain number of instances gone the length of complete extirpation of the entire cervical sympathetic chain on both sides of the neck, and judging from photographic illustrations before and after the operation this line of treatment must be admitted to have supplied most favourable results in Professor Jonnesco's hands. In view of the result of the surgical removal of this portion of the peripheral nervous system our conception of its physiological functions evidently demands reconsideration, for as the result of the operation Professor Jonnesco assures us that none of the sequelæ which physiologists have led us to suppose would be the inevitable result of extirpation have followed. Indeed no dystrophic results were noticed in the vital organs such as the lungs or the heart, or in the less important tissues such as the skin. The third paper to which we would draw attention has been prepared at the request of Professor Pavloff of the Imperial Institute of St Petersburg by Dr Bodissof. In this paper are described in length and detail the results of experiments on the glands of the stomach and buccal cavity by means of a special method of research. With regard to the gastric secretion, to examine its mode of production and its action Professor Pavloff has modified the method employed by Heidenheim and has secured for direct observation a form of accessory stomach shut off from the main cavity by means of a septum of invaginated mucous membrane. By this method of procedure the continuity of the filaments of the pneumogastric nerve has not been interfered with and hence the nervous mechanism of the accessory stomach can act in unison with that of the main viscus. The results obtained by this method have very important bearings on the therapeutic management of the processes of digestion, for it has been shown that the stomach is capable of secreting a gastric juice by the direct stimulation of its mucous membrane by chemical irritants and by certain extractive matter and also by psychical impressions reaching it from the central nervous system by way of the pneumogastric nerve. It has further been shown by the same method of research that certain substances which were generally supposed to excite the secretion of the gastric juice have apart from psychical impressions a negative influence on the activity of the glands of the stomach. For instance, pure albumin introduced into the stomach apart from psychical influences has no stimulating effect on the secretion, indeed, it remains as an inert substance in the stomach at the mercy of putrefactive processes It has been shown, then, that psychical influences reaching the stomach by way of the pneumogastric nerve have an even greater bearing on the processes of digestion than has heretofore been believed and failure to keep animals alive after resection of both pneumogastric nerves has been proved by Professor Pavloff to be due to the cutting off of the psychical impressions. By the appreciation of this fact and by the substitution of suitable direct stimuli of the mucous membrane he has been enabled to keep animals so operated upon alive for considerable periods of time This paper is to be continued in a future number of this series and will deal with the interesting and important relationship between pancreatic and intestinal secretion in association with gastric activity Apart from the three papers referred to the contributions to this volume are of little importance and some of them are extremely dull and uninteresting

---

Practical Dietetics. With Special Reference to Diet in Disease By W GILMAN THOMPSON, M D, Professor of Medicine in the Cornell University Medical College, New York. Second edition, enlarged and thoroughly revised. London Henry Kimpton. 1902. Pp 828 Price 21s

THIS is a very substantial volume devoted to the practical application of dietetic principles in health and disease. At the outset the author is disposed to complain that the dietetic treatment of disease has not received that attention in medical literature which it deserves and he expresses regret that in the curriculum of medical colleges the subject is usually either omitted or is disposed of in one or two brief lectures at the end of a course in general therapeutics To what extent these remarks apply in the United States we are not aware, but certainly in this country the subject of diet takes no subordinate position in the medical curriculum Indeed, the subject of special dietetics has received perhaps more attention in this country than elsewhere during the last ten years or so and at the present time we have a number of active workers in this field amongst us. The part that English investigators have taken is evident from the number of references that invariably occur in standard works published in other countries and the work before us is no exception, for we find ample references to the researches of Dr I Burney Yeo Dr F W Pavy Dr Roberts Sir Dyce Duckworth, Sir Henry Thompson Dr A. E. Garrod, Dr A P Luff, Dr Bence Jones, Sir Andrew Clark, and many others.

The work is divided into nine parts, of which the first is the most voluminous, consisting of over 200 pages. It deals with foods and food preparations special attention being given to those points regarding the nature and composition of food which render it either available or not available for a special purpose. There is a very interesting chapter on milk and its adulteration and impurities. There is no doubt that the United States are ahead of this country in regard to taking steps for the prevention of the adulteration and contamination of milk and for the maintenance of a high degree of purity The minimum limit for fat, for instance in the United States is 3·5 per cent, whereas in this country it is 3 per cent. The question of preservatives in milk does not, however seem to have reached a final decision, for only some weeks ago we were told that it was proposed to carry out a very practical experiment upon the subject by submitting to one set of individuals food preserved with certain

This is true, but what would its application be if it were not worked up into a spirit called whisky? The time has come, we hold, when some control should be exercised over the blending of spirits and over the labeling of the bottles containing them. The original word "whisky" had no reference at all to silent spirit but to spirit made from barley malt and why should it be different now? Speaking of whisky generally, the author states that whatever may be the cause of certain physiological effects resulting from the consumption of new or unmatured spirit it is a matter of ordinary experience that proper maturing does away with them and there can be no question that this is due either to change of objectionable substances into non objectionable or to their removal by absorption into the wood of the cask. We have given some attention to this subject and we are not able to affirm that any artificial maturing process can claim to do what time does. The author's remarks on the differences between the keeping powers of English brewed beer and lager beer are of interest. Lager beer, he states, is more prone to adverse changes from bacteria and "wild" yeast than is English beer under similar conditions of storage. By the pasteurising process, however, we have known lager beer to keep in excellent condition for years The author writes from Burton on Trent, so that it may be safely assumed that he has practical acquaintance with the great brewing processes In the work before us he has written a very instructive account of the alcoholic industrial processes, which is all the more valuable because it is presented in the light of modern knowledge.

The Testing of Chemical Reagents for Purity By Dr C KRAUCH Authorised translation of the third edition. By J A WILLIAMSON, F C S, and L W DUPRÉ. London Maclaren and Son 1902 Pp 350 Price 12s 6d—A schedule of the common impurities of those reagents which used in analyses and research is of the utmost value. Frequently in the work of chemical investigation puzzling results are obtained which are ultimately explained by the presence of impurities in the reagents used. The information as to the kind of impurity to which a certain chemical reagent is liable is not always to be found in ordinary text-books and therefore chemists, analysts, and others will welcome the publication of this book which deals with the impurities commonly found in reagents and with the means of recognising them Curiously enough the reagent that happened to suggest itself first to our mind was glycerine, especially in regard to the detection in it of arsenic in small amount as an impurity, but by some oversight glycerine is not even mentioned, although we find described many other organic compounds, such as cane sugar, carbolic acid, gallic acid, benzene, picric acid, and acetone. The plan of the work is simple enough, the various reagents and substances being arranged in alphabetical order We observe that in addition to references being given to original communications in foreign literature mention is also made where possible of the appearance of any abstract of the original in English journals So far as we have examined the sections the methods of testing described and those laid down for the quantitative estimation of the chemical agent under consideration are satisfactory As regards sulphuric acid, it is suggested that the Marsh test should be employed for the detection of arsenic We know no method that is simpler for rapidly differentiating an arsenical acid from a non arsenical acid than that of adding a few drops of sodium sulphide solution directly to the acid. In the presence of even a small amount of arsenic a yellow curd of arsenious sulphide at once separates which it is impossible to confound with sulphur The test was suggested by Mr Vincent Edwards, F I C, F C S, chemist to the Lawes Chemical Manure Company, and if it had been adopted in the case of the acid which was afterwards proved to contaminate beer with arsenic there would have been no beer poisoning epidemic. We commend this book because its chapters serve as a warning against certain possible pitfalls in chemical analysis arising from the impurities in the reagents employed.

JOURNALS AND MAGAZINES

The Quarterly Journal of Microscopical Science Edited by E. RAY LANKESTER, F R S, with the coöperation of ADAM SEDGWICK, F R S, W F R. WELDON, F R S., and SYDNEY J HICKSON, F R S With Lithographic Plates and Engravings on wood. London J and A. Churchill Vol. XVI., Part 4 (New Series, No. 184) Pp. 274. February, 1903. Price 10s—The articles contained in this part are the following —1. The Movements and Reactions of Fresh Water Planarians a Study in Animal Behaviour, by Raymond Pearl, Ph D, instructor in zoology in the University of Michigan, U S A. The author first studied all the normal movements of the ordinary planariæ, especially planaria doroto-cephala and planaria maculata, their food reactions and their reactions to chemicals in general, their electrotaxis, thigmotaxis, and rheotaxis, the righting reaction, the reaction of cut and regenerating pieces and hydrotaxis and the reactions during desiccation, but no work was done on the phototaxis or thermotaxis He shows that the planariæ are highly sensitive to slight mechanical shocks They secrete mucus threads of various form, they have periods of activity and rest, they have a disposition to collect together and to form groups, they are carnivorous A description is given of the cilia and of the mode in which they effect locomotion, a very full account is also given of the various movements of locomotion and of the movements consequent on the application of feeble and of strong stimuli. The article is a very interesting one. 2. On the Diplochorda, by A. T Masterman, M A., D Sc., lecturer on zoology, School of Medicine, Edinburgh. This constitutes Part 4 of Dr Masterman's researches on this group of Diplochorda and is devoted to Cephalodiscus dodecalophus It is illustrated by two plates. 3. On Hypurgon Skeati, a New Genus and Species of Compound Ascidians, by Igerna B J Sollas, B Sc. Lond, Bathurst student of Newnham College, with two plates. 4. The Anatomy of Arenicola Assimilis, Ehlers, and of a New Variety of the Species, with some observations on the post-larval stages, by J H. Ashworth, D Sc., lecturer on invertebrate zoology in the University of Edinburgh, with two plates. This number of the Journal contains the index to Vol. XVI

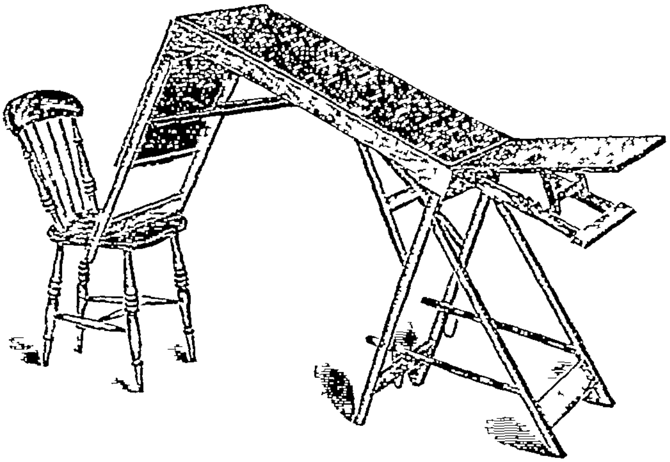
The Journal of Physiology Edited by Sir MICHAEL FOSTER, F R S and J N LANGLEY, F R S Vol. XXIX, No I Feb 23rd, 1902 London C J Clay and Sons. Pp 96 Price 6s—The present number of this journal contains the following articles —1 The Sugars of Muscle, by W A. Osborne and S Zobel. Amongst other conclusions at which the authors arrive the more important are that the diastatic action of pancreatic juice and malt diastase at a temperature of 37° C ends with the formation of maltose, and that the carbohydrates of muscle, exclusive of glycogen, are dextrins, dextrose, and maltose, the latter sugar preponderating 2. Further Observations of the Sequence of Changes produced in the Urine as a Result of Exercise, by G O Garratt. The exercise taken by the author was 45 miles per diem on a cycle with regulated diet at an average speed of 15 5 miles per hour, no rest or refreshment was taken. The urea was found to be very low during the ride but it rose abruptly after, reaching its maximum in eight hours The increased excretion of nitrogen fell almost entirely on the urea component. The excretion of ammonia was unaltered. The quantities of sulphuric acid and potassium were considerably increased in the urine, the maximum output occurring several hours before that of total nitrogen

Phosphoric acid was also discharged in larger quantities 3 Cortex Cerebri and Iris, by N Mislawski, professor of physiology in the University of Kazan This observer finds that dilatation of the pupil follows excitation of the cortex cerebri after section of the cervical sympathetic, after extirpation of the superior cervical ganglion, after section of the spinal cord at the first vertebra, and even after section of the medulla oblongata behind the corpora quadrigemina. 4. The Effect of Hæmorrhage upon the Composition of the Normal Blood, compared to its Effect during the Administration of Iron and Arsenic, by E. P, Baumann, M.D 5 On the Physiological Action of the Kenyak Dart Poison Ipoh and its Active Principle Antiarin, by C G Seligman, M.B Lond., with three figures in the text Ipoh is obtained from the crude sap of antiaris toxicaria indigenous in the Baram district of Borneo 6. Observations on Some Spinal Reflexes and the Interconnexion of Spinal Segments, by C S. Sherrington, F R.S , and E. E. Laslett, M.D Vict The number also contains the proceedings of the Physiological Society on Dec. 13th, 1902, and Jan 17th, 1903.

New Inventions.

A PORTABLE TABLE ALLOWING OF PATIENTS BEING READILY PLACED IN THE TRENDELENBURG POSITION

THE portable operating table shown in the accompanying illustration is a modification of that suggested by Mr Jordan Lloyd. Two legs are added under the head which are united to the upper ends of the ordinary legs by strong hinges and to one another below by a cross piece These can be fixed at the required angle to the ordinary legs by means of an adjustable support, one on each side. All that is necessary to place a patient in the Trendelenburg position is—first, to fix the extra legs at the necessary angle, secondly, to slide in the support for the foot flap and to drop it, and thirdly to tilt the table backwards and place an ordinary wooden chair under the cross piece connecting the legs at its foot.



It will really be found simpler to place a patient in the necessary position with this little table than with many of the operating tables in hospital theatres and I hope that it will supply a want which I personally have long felt existed.

The table as described above has been strongly and neatly made for me by Messrs. Maw Son, and Sons of Aldersgate street, London, E C

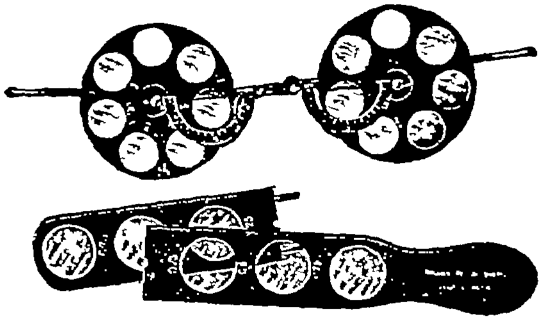
ARTHUR H. BUCK, F R.C S Edin.,
Brighton. Assistant Surgeon Sussex County Hospital &c.

A PORTABLE REFRACTOMETER.

FROM a model of a refractometer which I showed recently before the Ophthalmological Society Messrs. S Maw, Son and Sons, of Aldersgate-street, London, E.C , have made a standard pattern which is figured below

The instrument was designed to save the time and labour expended in changing the lens during retinoscopy, but it will doubtless prove of value to surgeons in the country and abroad for subjective examinations when the larger test cases may be impracticable, for the whole—face-piece, "rule," and eight complementary lenses and stops—packed in its case measures nine by three and a quarter by one and quarter inches and weighs 11 ounces, a less bulk and weight than the common yellow backed novel.

The plan of the instrument is simple. To each outer extremity of the face piece of a skeleton trial-frame is affixed a pivot, upon each pivot there rotates a disc. The discs (three inches in diameter) are perforated by seven holes (three-quarters of an inch in diameter), one is open and six are glazed with lenses from 1 D to 6 D the disc of one side with + lenses, the other with − lenses By rotating the discs the lenses come in succession before the eye hole, and since the instrument is reversible either disc may be placed before the eye to be examined. If a higher sphere than 6 D is desired a 7 D , or, if necessary, 14 D , lens is placed in the "cell" hanging in front of the eye-hole, so that by rotating the disc as before from 1 D to 20 D are obtained. For fractions of a dioptre an independent flat rule carrying six lenses + and − 0 25 0 5, and 0 75, with a space, is provided , this 'fraction rule ' is held vertically before the eye first at the central space, then raised or lowered as + or − fractions may be desired. The "cells ' in front of the discs for the reception of additional lenses are held in such a manner that on reversing the instrument each "cell" automatically retains the pendent position and so is ready to receive the lenses They bear the usual degree markings The frame is adjustable for binocular inter pupillary distance from two and a quarter inches to two and three quarters inches by a sliding bar bridge and thumb screw, for monocular use from two inches to three inches I P D can be obtained by simply displacing the bar bridge from right to left, or reversely, as needed The lenses provide all values from 0 25 D to 20 D + and − spheres, for monocular purposes , and for binocular vision all values from 0 25 D to 14 D , both + and − spheres. For the determination of astigmatism by retinoscopy the value of each meridian is determined by its spherical correction. In cases where subjective correction alone is sought, it is best estimated by the use of the stenopœic slit, the method to which Donders in his classical work accords premier position (retinoscopy was then unknown)



I believe that the arrangements of the instrument so far follow natural habit in procuring handiness of those lenses most commonly required under 6 D that it will be useful to these frequently practising retinoscopy Its value to surgeons away from their normal base or in the services will, I think, be unquestioned It is neatly and strongly made, there is nothing likely to get out of order, and its price is low

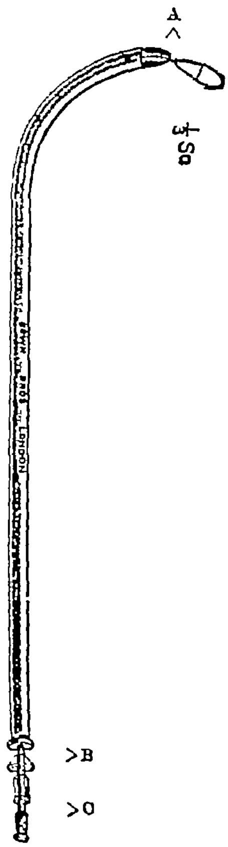
A NEW SILVER CATHETER.

HAVING frequently met with difficulty in withdrawing urine from the bladder of patients suffering from retention due to stricture, enlarged prostate, &c., owing to the eyes of the ordinary silver catheters becoming blocked with blood clot during their passage through the urethra, I have devised a new instrument to cope with this difficulty, whilst at the same time it possesses a great advantage over the ordinary catheter in that the inside of the instrument can be properly cleaned and rendered absolutely aseptic.

The principle of the instrument can be at once seen from the accompanying illustration and, briefly, its construction differs from the ordinary catheter in that the last half inch of the instrument is continuous with the stilette and not with the catheter itself By this means it can be moved in or out of position by pulling or pushing the end of the stilette and thus there is no necessity for any opening in the side of the instrument

To use the catheter the stilette is pulled upon until the distal end is in position and the instrument is then passed into the bladder By pushing on the end of the stilette the end of the catheter is now displaced and the urine is drawn off, the end of the instrument is then replaced and the catheter is withdrawn



The advantages claimed for this new instrument over the present type are —1 The absolute impossibility of the catheter becoming obstructed with blood clot or other foreign material during its passage into the bladder, for during this manipulation there is no opening whatever in the instrument. 2. The ease with which the flow can be regulated according to the distance the stilette is moved. 3 The rapidity with which the bladder can be emptied owing to the larger opening when the end is thoroughly displaced. (N B —In testing this instrument I found that a No 12 ordinary silver catheter occupied 41 seconds in emptying one pint of water, whilst with this instrument (also a No. 12) it was done in 30 seconds) 4 Supposing the eyes of the ordinary instrument to become obstructed with blood clot in the bladder there is no way of removing it excepting by taking out the instrument altogether, whilst if the open end of this instrument becomes so blocked the clot can be broken up by alternately shutting and opening the end by means of the stilette and without taking the catheter out. 5 Its greater adaptability to asepsis, for when the instrument has been used the end is unscrewed and the small button (B) is taken off the stilette. The stilette is then withdrawn by means of the end A and the inside of the catheter is thoroughly washed by a stream of water The stilette is then replaced and the end O is screwed on A piece of gauze is afterwards passed through O and the stilette is again withdrawn, carrying the gauze with it which thoroughly dries the inside.

As yet I have only had the opportunity of using the instrument in a small number of cases, but in all of these it has answered admirably and has quite fulfilled all my expectations

In conclusion I have to say that the drawing has been prepared and the instrument has been made by Messrs. Down Bros, Limited, of St. Thomas's street, Borough, London, S.E., from whom it can be obtained

A SEPTOTOME FOR USE IN MOURE'S AND OTHER OPERATIONS FOR DEFLECTION OF THE TRIANGULAR CARTILAGE.

THIS instrument is a pair of detachable cutting forceps adapted from existing patterns, but specially devised to amplify the applicability of Moure's valuable operation for the rectification of the various forms of deflection or deviation of the nasal septum. The blades are modified from those of Moure's scissors from which they differ in being narrower and symmetrical, their cutting edges are but slightly divergent above and they are obtuse—somewhat probe pointed—at the extremity The consequence is that these blades can enter contracted fossæ and be insinuated to the required depth without endangering the folds of the limen vestibuli or the inferior turbinals, whilst the heels are sufficiently apart to clear the septum mobile. The shanks are much less curved or bowed, and at their junction with the blades there is no bending on the flat, in fact the remainder of the instrument closely follows the straight cutting forceps of Asch, but there is an addition of two powerful springs, and the result of the combination is a simple and handy septotome which works well in practice. The springs insure the disengagement of the blades after closure upon the septum, an action which greatly facilitates an extension of the primary incision, especially of the maxillary one towards the naso-pharynx, upon which, I think, so much of the success of the operation often depends. Strength is secured by the Asch form of handles, whereas the absence of an angle in the shanks, combined with symmetry in the blades, helps to maintain precision in keeping the line. For better adaptation to different requirements—such as the age of the patient, the fancy of the operator, and other conditions—the septotome can be had in three sizes, varying only in the length of the blades, No 1 measuring half an inch, No. 2 three-quarters of an inch, and No 3 seven eighths of an inch (1 3, 1 8, and 2 3 centimetres respectively) Of these No. 1 has, perhaps, the widest application, but the medium size answers in nearly every case, and the length from pivot to point of blade is the same in all. The septotome was made for me by Messrs Mayer and Meltzer

REVIEW[1]

A Treatise on Moxa as applicable more particularly to Stiff Joints By JAMES BOYLE Esq, Surgeon of the Middlesex Infirmary, &c. 8vo pp 168. *London, 1825* Callow and Wilson

THE use of this species of cautery appears to have originated with the Japanese, by whom, and other Oriental nations, it has been much employed. The origin of the term *Moxa* has been a frequent subject of dispute among etymologists, but if it be not immediately derived from a word in the Japanese, nothing more than ingenious conjecture can establish its origin from other tongues. In France, the publication of Baron Larry's work on the subject procured it the sanction of many members of the profession, but, in England, little encouragement has yet been given to a practice which, to say the least of it, is decidedly unpopular, and opposed to the feelings and opinions of our countrymen.

---

[1] A portion only has been transcribed

We shall now extract from the author's book a part of the History of Moxa, which will show well enough the progress it has made and the class of practitioners by whom it has been most employed.

"The word moxa, according to the inhabitants of China and Japan, designates a cylinder formed of a cottonous species of mugwort (*Artemisia Chinensis*). The date of its first introduction into notice, as a therapeutical agent, is not to be found amongst the records of its history; but at the earliest period to which it can be traced, it was considered an infallible remedy in the cure of many diseases, particularly gout, chronic rheumatism, and nervous disorders.

From China and Japan moxa was introduced into the western part of the continent of Asia; thence amongst the Chaldeans and Egyptians, by whom, in progress of time, its use was in some degree modified. From these ancient nations this heroic remedy was conveyed into Europe, where, occasionally, or rather in proportion to the success of the practitioner who employed it, its virtues have been recognised or discredited. Its efficacy however has been acknowledged by almost every nation; yet the mode of preparing it for use, as well as the manner of applying it, have much varied.

The Chinese formed a small pyramid, by rubbing the dried leaves of the mugwort between the hands, for the purpose of obtaining the cotton from the fibrous part; a little very fine tow being made to project from its summit, which latter being lighted, the material was allowed to burn down gently. The Indians were accustomed to form theirs of a species of rush, which was permitted to burn down in the same manner. The Persians employed goat's dung dried and rolled into cylinders. The Armenians, the agaric of the oak. The Thessalonians made use of a particular moss. The Laplanders employed birch wood, in a rotten and phosphorescent state. The Egyptians, we have reason to believe, were the first who had recourse to cotton, and the civilised nations of Europe have successively adopted this material, with some modifications."

'Thevenot and Belloni inform us, that the Turks and Armenians attach the greatest importance to moxa; and the first historians, upon describing America, after the discovery of the New World by Christopher Columbus, attest that the employment of fire was not less known to the inhabitants of that vast continent than to those of the old world.'

In the year 1755 the Academy of Surgeons in France, with a view of ascertaining the real advantages of fire in the healing art, the cases in which it was most likely to be successful, and the most efficient mode of applying it, instituted certain inquiries for the purpose. Professor Percy was elected to report from experiment and practice. Various modes of applying heat, from the concentrated rays of the sun to the actual cautery were put into requisition; but as a full detail of the measures adopted would be rather tedious than useful, it may suffice to state here, that the investigation was favourable to the reputation and revival of this ancient remedy. Thus was again brought forward the most powerful and successful agent which we possess in the treatment of chronic disease.

To those persons who may wish to make trial of the moxa, and to whom the work of BARON LARREY is inaccessible, Mr. BOYLE'S book may be of service. We think, however that the whole might have been embodied in a communication or two to any respectable journal. It is obvious enough that the remedy is of too painful a nature to be much employed in private practice, and the trials which have been made of it in our public hospitals have not demonstrated its superiority to many other modes of procedure.

CRIMINAL STATISTICS.

THE first part of the "Criminal Statistics of England and Wales in 1901" has been issued prefaced with an introduction by Mr. H. B. Simpson, one of the chief clerks of the Home Office. This gentleman observes that the figures for 1901, as compared with those for 1900, point to an increase of crime which is unmistakeable but not of serious magnitude, and, further, that this has taken place both in the case of indictable offences, which have of late years shown a marked tendency to diminish, and also in the case of non-indictable offences—that is to say, those dealt with at police-courts which since 1886 have more or less steadily increased. In one class of offence this increase is attributed in part to the creation of the new charge of habitual drunkenness and also to the steady growth in the number of attempted suicides which are brought to the cognisance of the courts. Charges of habitual drunkenness were made in 176 cases, against 36 males and 140 females. Of these one was withdrawn, 156 resulted in summary conviction, and 19 of the persons accused were committed for trial and convicted. Turning to the tables which deal with coroners' inquests we find that the total number of inquests in 1901 was 37,184, held upon the bodies of 24,072 males and 13,112 females. This appears to be a pretty constant figure, for comparison with the corresponding tables for 1900 and 1899 shows that the totals in those years were 37,076 and 37,026 respectively, while the males and females were divided in practically corresponding proportions. The slight increase observable in 1901 is more than accounted for by an appreciably larger number of murders and suicides. In that year coroners' juries returned verdicts of murder in 208 cases, as against 145 in 1900 and 142 in 1899, and of suicide (omitting cases of *felo-de-se*) in 3057 cases, as against 2806 in 1900 and 2780 in 1899. In 37 of the cases of murder the person whom the coroner's jury found guilty of the crime had taken his own life at the time of the murder. It would be interesting to know, if the information were obtainable, in how many of these cases of murder and suicide committed simultaneously the cheap revolver was responsible for the double tragedy and also the part which it played in the suicides unaccompanied by murder and in the accidental deaths. A table which gives the number of inquests upon the bodies of children suffocated whilst in bed with their parents or others informs us that 1538 of these inquiries were held in 1901, a smaller number than in either of the two preceding years, and that in 1434 instances the verdict was "accidental death." A verdict of murder was, however, found in one instance, a verdict of manslaughter in four, and an open verdict in 99. The increasing accommodation provided for habitual inebriates and the increasing extent to which advantage is taken of the law with regard to them are shown by the figures relating to their reception in inebriate reformatories. In 1899, the first year of these institutions, only 88 persons were received into them; in 1900, 144; and in 1901, 204. A small increase is observable in the number of criminal lunatics in detention. At the end of 1901 there were 791 of these; at the end of 1900, 770; and at the end of 1899, 766. Most of these are persons ordered by the court trying them to be detained during His Majesty's pleasure. In 88 cases, however, out of the total of 791 the prisoner was certified insane before trial and in 73 after trial, so that it will be seen that the interest of the State in the criminal's mental condition is not limited to the inquiry held or omitted to be held when he is charged with an offence. The total given it will be observed includes those previously confined at Broadmoor and elsewhere, as well as those committed to asylums in the year under discussion. The number of those confined as of unsound mind on the last day of 1901, who had been so confined for one year or less was 109; on the corresponding day of 1900 it was 89; and on that of 1899 it was 77. With regard, however, to the apparent increase in the number of criminal lunatics as shown by such returns as those before us, Mr. John Macdonell, C.B., LL.D., who wrote the introduction to the Criminal Statistics of 1899, thus recorded his opinion: "It is often alleged that insanity is increasing; that juries are more and more disposed, at all events in the case of grave crimes, to find the accused insane; and that consequently an increased proportion of insanity among criminals is to be expected. These statements are not borne out by the available statistics on the subject. No doubt there are several reasons why they should be read with caution, one being the fact that there is no record of persons who are tried summarily and found insane—that is to say, no information as to nine-tenths of the persons convicted. But so far as the available figures go they show no increase of insanity in the criminal classes, or, to be more accurate, in the disposition to find insanity as a concomitant of crime.

Royal Medical Benevolent College

Patron—HIS MOST GRACIOUS MAJESTY THE KING
President—THE RIGHT HON THE EARL OF ROSEBERY, K G
Treasurer—CONSTANTINE HOLMAN, M D

JUBILEE SPECIAL APPEAL

The Council has the pleasure to announce that HIS ROYAL HIGHNESS THE PRINCE OF WALES has graciously consented to take the Chair at a FESTIVAL DINNER on the 10th June, in aid of the funds of the Charity, and it is the earnest wish of His Royal Highness and of the Council that a sum of £10,000 should be collected on that occasion, which amount would relieve the Institution of its financial embarrassment.

From time to time the Council has been compelled to make special appeals for Funds, and in spite of the assistance derived from one issued late last year, a sum of £2,900 was owing to the Bankers at the end of 1902 Since then the Council has had to remedy defective structures at Epsom College, which will cost a considerable sum of money, and they feel that a serious effort ought to be made to put the finances of the Institution on a sound basis

The 6th of July will be the 50th Anniversary of the laying of the foundation stone of the College, and the present appears to be a fitting occasion to raise a fund to enable the Council to repay money due to the Bankers, to pay all current liabilities, which are very heavy, to repurchase stock which was recently sold, and to leave a balance in hand for contingencies

The Royal Medical Benevolent College provides pensions for Aged Medical Men, and the Widows of Medical Men, in reduced circumstances, and a School, open to all classes, but offering special advantages to the Sons of Medical Men, fifty of whom are Foundation Scholars

There are Fifty Pensioners who receive £30 a year each They must be legally qualified Medical Men, who have been registered Medical Practitioners for five years, or the Widows of such

Fifty Foundation Scholars receive an education of the highest class, and are boarded, clothed, and maintained at the expense of the College They must be elected, after approval by the Council, from among the necessitous Sons of such Medical Men as would be professionally qualified for Pensionerships

A sum of over £6,000 is required annually for the benevolent side of the Institution, and the greater part of this amount is derived from voluntary contributions In recent years considerable sums of money have been spent in remedying structural and sanitary defects at the College, the buildings being close upon 50 years old

The Council has sought for many years to keep the numbers of both Pensioners and Foundation Scholars at 50, but this cannot be continued unless the income of the Charity be maintained

Donors of Ten Guineas, in not more than two payments, and Collectors of Twenty Guineas are Life Governors of the College, Subscribers of One Guinea annually are Governors during the continuance of their Subscriptions Contributions of a less amount than One Guinea are welcome

The Council trusts that Medical Men will do all in their power to make this Jubilee Special Appeal a financial success Gentlemen willing to act as Stewards on the occasion of the Festival Dinner should send their names to the Secretary as soon as possible The office does not involve any pecuniary responsibility

GEORGE P FIELD, Chairman of the Dinner Committee
J BERNARD LAMB, Secretary

Office 37, Soho Square, W

THE LANCET.

LONDON SATURDAY MARCH 7, 1903

The Limitations of the General Medical Council

WE have upon a previous occasion pointed out that both among the general public and also among members of the medical profession a great amount of ignorance exists as to the powers and duties of the General Medical Council.[1] The minutes of a meeting of the Executive Committee which was held on Feb 23rd are now before us and the questions submitted to this committee show very well what we mean by the above-mentioned ignorance. Mr EDWARD DENNIS VINRACE asked for ' an authoritative ruling " upon the question whether or not members of the staffs of hospitals should sign school board certificates for children under their care. To this question a resolution of the committee stated that "the question raised is not one which comes within the scope of the committee s functions and the Executive Committee are therefore not in a position to give the authoritative ruling which Mr VINRACE desires" Another question submitted by Dr. W H. BROOK asked whether a registered practitioner was allowed to administer anæsthetics for a dentist who was on the Dental Register, but who was acting as extractor to a dental company duly registered under the Companies Act but the members of which company were not on the Dental Register To this the Executive Committee replied in the terms of the deliverance on the subject already given by the General Medical Council. This deliverance was to the effect that any registered medical practitioner who knowingly and wilfully assisted a person who was not registered as a dentist in performing any operation in dental surgery was liable on proof of the facts to be dealt with by the General Medical Council as having been guilty of infamous conduct in a professional respect. The Executive Committee confessed that it could give Dr BROOK no further answer Another question submitted by Mr RUSSELL RUBENS asked whether a medical man who attended a child after he had been circumcised by a Jewish 'mohel" and unskilfully treated, or who gave a certificate after death (of such child) would be considered guilty of covering To this the committee replied that it had no jurisdiction over unqualified practitioners but that it is prepared to consider any complaint as to any unprofessional conduct on the part of any medical practitioner

Now these questions and the replies thereto show very well the limitations of the General Medical Council. It is unfortunate that the full title of the General Medical Council is somewhat cumbrous for daily use, for it shows what that body is. It is the General Council of Medical Education and Registration of the United Kingdom. It was created by the Medical Act of 1858 to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. Its statutory duties are to look after the education of medical students and the registration of qualified medical men. It is not a medical protection society, or a medical trade-union, or a medical trade guild, or a medical defence union. It deals with one offence only—namely, 'infamous conduct in a professional respect"—and under this head come such varying offences as advertising or the commission of adultery with a patient The Council can only inflict one penalty—the removal of the offender's name from the Register—and such removal in no way precludes him from practising provided that he does not use any name or title implying that he is still registered. It will thus be seen that the General Medical Council has no power, however much it may have the desire, to answer or to deal with such questions as those which we have set out above They are mainly questions with which we have dealt again and again in our columns. Mr VINRACE mentioned in his question that some hospital medical men refused to sign school board certificates because they considered that to do so was injurious to the general interests of the profession. Although this point has not hitherto come before us yet we have always insisted that a medical practitioner should not give a school board certificate if such certificate is liable to be "revised ' by an unqualified person. Dr BROOK S question involves a conflict between the letter and the spirit of the law Technically speaking there is no reason why a medical man should not administer an anæsthetic for a registered dentist, and there was no question as to the registration of the dentist to whom Dr BROOK referred. But, as Mr. C S TOMES pointed out in a letter to the registrar, a medical man giving an anæsthetic for a registered dentist who is acting for a company of unqualified men is indirectly encouraging "a state of things of which he must disapprove." The question as to circumcision, again, is practically one which raises the whole matter of unqualified practice. In our opinion no medical man should refuse to treat a child who is suffering in consequence of the negligence or ignorance of a "mohel,' but in case of the child s death the medical man should refuse to give a certificate and should at once inform the coroner of the facts

As the law at present stands unqualified practice is absolutely legal Any person however ignorant, however dirty in his methods, may treat any patient, may prescribe any poison, may give away any poison, may administer an anæsthetic, or may perform or try to perform any operation on anyone who is fool enough to submit himself or herself for treatment So long as the unqualified practitioner does not imply that he is registered or refrains from *selling* a scheduled poison, and provided that the victim whom he treats does not die, the law itself *to say* nothing of the General Medical Council, is absolutely powerless That this state of things should exist is neither more *nor less than a scandal and the* only possible reason why the law allows it is that it considers that a man has a right to do as he pleases with his own body so long as he does not interfere with the health of his neighbour's body But it is useless to blame the General Medical Council for not interfering in a state of matters over which it has no control

---

[1] THE LANCET August 30th, 1902, p 574

A solicitor who is struck off the rolls by the High Court at the instance of the Incorporated Law Society, or who even fails to pay for his annual certificate, or a barrister who is disbarred is thereby precluded from practising A medical man who is struck off the Register can still practise. His only disabilities are that he is unable to sign a death certificate, to sue for fees, and to hold certain public appointments

In order that the General Medical Council should have more power it is necessary that the law as to unqualified practice should be amended. Unqualified practice should either be made illegal or, if that be considered impracticable, a licence should be made obligatory and such licence should be made to cost a very large sum. It need not be any guarantee of knowledge or skill any more than a licence to sell beer or tobacco is any guarantee of the purity of the goods sold But if such licence were made to cost, say, £500 per annum the being struck off the Medical Register would be a punishment in reality instead of being, as at present in the case of the gross offender, little more than nominal.

◆

The Relation of Dyspepsia to Eye-strain

FEW terms are more familiar to the ear of the physician than that of "biliousness." By the laity it is held to constitute an altogether satisfactory explanation of a multitude of symptoms which, whilst collectively they produce much discomfort, are so inconstant in their seat and manifestation as to prevent their rising to the dignity of a definite disease Has a man some swimming in his head on rising he is "bilious", does he suffer from flatulence, nausea and want of appetite, from low spirits, and from inability to read without headache, he is "bilious." He proceeds to dose himself with salts and feeds himself on articles of diet which the advertisements assure him will promptly remove every ill At length, failing to obtain relief by these means, he betakes himself to some prudent and experienced practitioner who, casting about for the hidden cause of his patient's troubles, minutely inquires into his habits of life, his diet, the state of his alimentary canal, his allowance of tobacco and of alcohol, and the time he can devote to exercise Sometimes the answers to all these questions are atisfactory, while sometimes modifications can be suggested and some degree of improvement generally follows, if not, then mental worry or, it may be, uterine trouble is diagnosed and rest, change of air and scene, or a system of topical treatment is advised and adopted. Then again a partial or complete restoration to health is effected and the ordinary avocation is resumed But the cure is soon found to have been, like the former, only temporary The dyspeptic symptoms and the disposition to look at the dark rather than at the bright side of things in general recur and with all this there are headache and incapacity to work or even to try to work. After a time the victim becomes inured to his troubles, ceases to apply remedies, finds out what is best for him, and rests satisfied that his disease is alike inscrutable and incurable.

Such is the life history of many distinguished literary and scientific men. In a highly suggestive volume[1] that has just been published Dr GEORGE GOULD of Philadelphia has selected as examples five well known men—DE QUINCEY, CARLYLE, DARWIN, HUXLEY, and BROWNING—all of whom, whilst daily performing a prodigious amount of work, were constantly complaining of dyspepsia, inability to read or to work, and headache. He endeavours to show that in all these cases the primary defect, the starting point of the whole train of symptoms, has hitherto been strangely over looked and is to be really found in some error of refraction in the eyes—such, for example, as hypermetropic or mixed astigmatism or some defect in the innervation of the extrinsic muscles of the globes. With this clue every thing, he maintains, becomes clear and the symptoms range themselves with those that are very familiar to the ophthalmic surgeon They are persistent because the cause is persistent. They disappear or are greatly relieved when work is given up and long walks or rides are taken in the open country and in the gloaming for the eyes are then no longer strained, they are increased on the resumption of literary or scientific work, for the efforts to obviate the defects are recommenced, the head ache, anorexia, and depression of spirits are all reflex phenomena well known in ophthalmic practice Lastly, they entirely disappear when the error of refraction is duly corrected by appropriate glasses. The conditions required for the recognition of a *vera causa* are fulfilled—*praesens morbum facit, sublata tollit*

It may, indeed, be said that the view here advanced proceeds naturally from the ophthalmic specialist and we are irresistibly reminded of the shoemaker who declared to the citizens of the beleaguered city that there was nothing like leather, but Dr GOULD is an accomplished physician and supports his opinion with so much ingenuity that our first disposition to smile gives place to the feeling that there is much to be said in its favour It is to be remembered that the healthy eye can bear an enormous amount of work without harm either to its own structure and functions or to those of the body at large, it is only the ill formed astigmatic or otherwise defective eyes which are compulsorily brought into play that are instrumental in inducing the long chain of symptoms that constitute the troublesome and obscure affections dyspepsia and hypochondria Our knowledge of the etiology of these conditions has been masked by the circumstance that the efforts of the patients to use their eyes are not made apparent by any marked symptoms of inflammation in these organs them selves, but are apt to excite a train of neuroses which have hitherto distracted the attention of physicians from the eyes and concentrated it upon the stomach, brain, or other organ to the distress of the patient and the opprobrium of medicine. Dr GOULD sometimes takes for granted what a Scotch jury would return as "Not proven." But it is clear that in every case in which the various symptoms commonly included under the terms chronic dyspepsia and 'bilious ness" are present and prove resistant to ordinary treatment it would be well to obtain the advice and opinion of an ophthalmic surgeon, for this can certainly do no harm and may quickly abolish the trouble and restore the patient to health

"Run Down"

THE claims of medicine to be ranked as one of the exact sciences meet no more formidable reproach than the undeniable one that certain ill-defined terms are used by some or all of its followers to cloak a multitude of vague disorders The most familiar perhaps of these is the universal "rheumatism," a term which even in these enlightened days is commonly employed to designate a number of disorders the pathology of which, if still to a large extent unknown, is at any rate, almost certainly of very diverse kinds Our ideas of rheumatic fever appear certainly, thanks to recent bacteriological researches, to have gained a foundation of exact knowledge, but he would be a rash physician who ventured to define the limits or the pathological essentiality of muscular rheumatism or of rheumatoid arthritis. We shall be told, no doubt, and confidently told, that the latter is, of course, a microbic affection When we ask for even a vestige of actual proof it will not be so easy to satisfy our demands.

Among the many conditions the circumstances of which are so familiar and the actual nature of which is so obscure, there is none perhaps more commonly met with than that which is known as the state of being "run down" The expression is a good one to describe a certain physical and mental state in our present ignorance of its pathogenesis. To say that a man is 'run down' conveys quite plainly to our minds that there is a general depression in the vitality of the organism, a depression that is widespread, embracing the purely physical as well as the intellectual functions, while at the same time the term gives no hint whatever as to the anatomical site or the pathological nature of the underlying cause. This negative nature of the name for a condition with which we are all only too familiar is unfortunately completely justified by an entire absence of exact pathological knowledge with reference to the condition itself Certain experiments and observations upon fatigue in school-children may bear definitely upon the point in question. Except these we can recall no positive knowledge bearing upon the state which we may suppose to be present in a person who is, as we say "run down. We cannot get much nearer to a definition of this condition than to describe it in wide terms as one of fatigue. We possess certainly a fair sum of chemico-physiological knowledge relating to fatigue so far as muscle tissue is concerned. As regards the fatigue of mental functions and of digestive, secretory, and absorptive functions we still know remarkably little This little we would probably express by saying that in the condition to which we are alluding there is a general depression of innervation, that the higher centres of the brain are depressed, and that there is a lowered condition also of all the organic functions resulting in an incomplete performance of digestion and assimilation, consequently in impoverished nutrition and also in impoverished power of muscular action. The resulting impoverished blood reacts upon the nervous system which is imperfectly fed and thus a vicious circle is completed

In the production of this condition, as it is most commonly seen, monotony of action—whether physical or mental—seems to play a very important part The typical case of a man who is "run down" is that of the business man who, with the regularity of a timepiece, goes from his breakfast table to his office chair, from his office chair to the luncheon-room, from luncheon to the office chair, and from the office home again in the evening This process repeated day after day, accompanied by an occasional attack of dyspepsia or of insomnia, or of extra business worry, tends to depress even an ordinarily healthy constitution. On the nervous or delicate the condition of being "run down" is frequently imposed before the machine-like existence has been many years, or even many months, in play Man is not meant for monotony A constant recurrence of the same activities, the same thoughts and the same associations appears to produce a dead level of mere weariness, even though the daily round is of itself made up of varying details. Thus, in the instance we have taken it might be thought that in the short railway journey, in the meeting of daily companions and in the little interval at luncheon enough variety would be imposed upon the city man's existence to save him from monotony But the variety is itself monotonous. He cannot vary his railway journey, he cannot vary his daily meetings, or even, in many cases, his place of luncheon, and so the daily round becomes wearisome, and the excursions for luncheon become as trying as the monotony of a sandwich in the office.

We have glanced at the pathology of the state of the man who is 'run down" and we have briefly alluded to one potent factor in the production of this condition. We may therefore in a few words suggest a remedy The nature of this will be obvious from what has just been said The first step towards saving us from getting run down will be taken if we can save ourselves from monotony At will a man cannot change his main daily occupation. As a business man, he must attend to his office work, as a professional man, he must execute the daily duties of his calling, and for most men the greater part of every 24 hours is thus absorbed. Even then, however there are little intervals and there are gaps before and after the actual working hours. It is here that a variety of pursuits should save the mind from the dulling effects of monotony The brain should be trained, so to speak, to switch itself off directly the opportunity occurs and instead of continuing to weary itself with the contemplation of business or professional complexities should revel as soon as active work is stopped in other intellectual fields. The pleasures and distractions of the society of one's fellow creatures, to some temperaments the most complete of all alleviations of worry, are not always at hand. But a hobby may be constantly accessible and it behoves all men who find themselves "run down' to make an attempt towards the enjoyment of some intellectual activity different from that constantly demanded by their daily occupation.

Regulations in regard to Cremation.

LEGISLATIVE sanction[1] has recently been accorded to cremation as a means of disposing of human remains in this country and consequently the practice is likely in future to supplant, to a greater or less extent, the ordinary custom of burial It is in its relation to the public health more especially that cremation has a peculiar interest for our profession, and if we regard it from this point of view exclusively, apart from religious sentiment, it will generally be admitted that the practice has very much to commend it. With an urban population increasing at even its present rate and with the consequent rapid disappearance of available cemetery land it is obvious that not many years can elapse before it will be simply impossible, with due regard to the safety of the living, to find ground for interment in the usual way, and this difficulty will, of course, be greatest in the neighbourhood of our great centres of population, such as London, Lancashire, parts of Yorkshire, and the Potteries, in none of which districts has the problem of the safe disposal of the dead even approximately been solved. Considerations of this kind have evidently weighed with the Government which only last year succeeded in placing upon the statute book an Act for legalising and regulating the practice of cremation in England. It is important to note that Section 7 of the Cremation Act imposes upon the Home Secretary the duty of framing regulations for the inspection and maintenance of crematoriums and also of prescribing the conditions under which the burning of human remains may take place Accordingly, in October last Mr AKERS-DOUGLAS appointed a departmental committee consisting of Mr TROUP and Mr BYRNE of the Home Office and Dr H FRANKLIN PARSONS of the Local Government Board, and their report, which has evidently been prepared with great ability and care, has been issued as a Blue book during the past week.

---

[1] Cremation Act, 1902 (2 Ed. VII., c. 8) Sec. 7

As regards the proposed regulations for the general management of crematoriums the committee has been largely guided by the experience of the English Cremation Society and by the rules drawn up for that society by its President, Sir HENRY THOMPSON But, as we should have expected, the portion of the subject which the committee has discussed with particular minuteness is that relating to the conditions in which, for the future, cremation ought to be permitted. Under this head the committee says "The point which we have considered of prime importance has been to frame regulations which, while avoiding unnecessary restrictions such as might discourage cremation or involve unnecessary delay in the disposal of the body, would reduce to a minimum the risk of cremation being used to destroy the evidence of murder by violence or poison." With the object of avoiding as far as practicable this risk the committee has carefully studied the records of past cases of murder and has directed special attention to the question of what certificates or other evidence of the cause of death had been produced before burial took place In some of these cases the committee found that the bodies of murdered persons had been buried without any certificate of the cause of death and it pointedly draws attention on more than one occasion, in the course of its report, to what we consider a scandalous fact, namely, that "the existing law permits the burial of a human body without medical testimony as to cause of death and even previous to registration of the death. Unless, therefore, some definite ground of suspicion arises there is no investigation of those cases where the cause of death is obscure and where the ambiguity of the symptoms can be slurred over in a certificate which it is no one's business to question or criticise."

In framing regulations having for their object the minimising of the danger of cremation being used to destroy evidence of crime, the committee had first to decide to whom should be intrusted the responsibility of authorising or of forbidding cremation in every individual case. After discussing certain alternatives, the committee advises that the person to decide this point should be a medical referee specially qualified for the work and appointed by the cremation authority The latter part of this recommendation appears to us, however, to be open to serious objection The person to whom such high responsibility is to be intrusted should be absolutely independent of the authority whose operations he is appointed to control The committee insists on the production in each case of two certificates of the cause of death, one from the medical attendant of the deceased and a second from an independent practitioner The trustworthiness and sufficiency of these certificates are to be decided upon by the medical referees, whose duty it is to require a post mortem examination by a pathological expert or a coroner's inquest as a condition precedent to cremation in any case in which the slightest suspicion attaches to the manner in which the death took place. The committee appends to its report the draft of a very complete and apparently satisfactory series of regulations with regard to the inspection and maintenance of crematoriums and also a schedule of forms of medical and other certificates to be used in cases of cremation. Incidentally the committee refers to matters of importance concerning the certification and registration of death which will, we trust, receive that attention which they undoubtedly deserve from the Registrar General and his staff. Most valuable evidence which has been published in its report, was given to the committee by Sir HENRY THOMPSON, Dr THOMAS STEVENSON, Dr G DANFORD THOMAS, and Dr H T HERRING The last-mentioned gentleman was unquestionably justified in expressing the opinion that the registrars of death ought to be "a little more literate" than they frequently are and this is especially desirable because at the present time they are the only men who have power to question certificates of death in cases that are not reported to the coroner

Annotations.

' Ne quid nimis

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST

THE Public Control Committee of the London County Council has made a report to the Council upon the subject of post-mortem examinations in inquest cases of a special nature, and the Council has adopted its recommendations The committee, as was announced in our columns, recently received deputations from the South West London Medical Society and from the medical and surgical staff of St. Thomas's Hospital, when representations were made as to the manner in which Mr Troutbeck interpreted the view of the Council that post-mortem examinations in cases of a special nature should be entrusted to a specially skilled pathologist. The members of the committee, having given full consideration to the matter, and having seen Mr Troutbeck and learned the number of inquests which he had held in his double capacity as coroner for the South-Western District of London and for Westminster, make suggestions which show that they are desirous of removing the grievances that are complained of ' We think,' the report runs, "that in cases where a medical practitioner had been in attendance, if it is intimated to coroners that whenever they are of opinion that the evidence of the medical attendance is material to the proper elucidation of the case he should be invited to be present at the post-mortem and summoned to give evidence at the inquest, although a pathologist may have been employed." This course, they add, has been suggested to them by Mr Troutbeck, and we are glad to learn this, for it implies that we shall hear no more of the coroner's officer being sent to get medical information from the professional adviser When medical evidence is required it will be given upon *subpœna* and the witness will, of course, be paid the statutory fee for his evidence. The report acknowledges the correctness of the view taken by THE LANCET that in the present state of the law the appointment of a salaried pathologist cannot be made by the London County Council but the committee recommends that it be authorised "to obtain the names of several competent pathologists who will be prepared to make post-mortem examinations and give evidence in special inquest cases at the fee of £2 2*s* per case." The line taken by the committee is evidently one of conciliation. When medical evidence is required it will be given upon *subpœna* and be duly paid for When a special pathologist is required—and nobody doubts that this contingency arises—it will be attempted to provide coroners with a list of medical men of recognised standing in the profession, from whom the expert witness may be chosen. Discretion must remain with the coroner to decide when medical evidence is essential to the finding of an incontrovertible verdict and when a case presents pathological features. In both cases a non medical coroner is placed at a disadvantage, but we trust that the medical men in Mr Troutbeck's districts will do him the justice of believing that he will try to act fairly towards them Their action in refusing to give medical evidence save upon *subpœna* has now been endorsed by the Control Committee of the London County Council and cannot again be impeached by anyone as childish or greedy Their feeling that a reflection on their competency is intended should be removed by finding that the expert witness is only to be called in special cases and will be chosen from men of standing in the medical profession.

WHICH IS THE GREATER OFFENCE?

WITH regard to several cases of fraud which were recorded in the papers last week it is interesting to consider the nature of the offences and the degree of punishment that was inflicted. Karl Frederick Kramer was convicted of committing a fraud against the excise. He was ingenious enough to import saccharin into this country under the name of sulphate of aniline. As a matter of fact the substance was a loose compound of saccharin and aniline from which the saccharin could easily be separated. The defendant managed to evade the duties and customs in this way for about a year He was ultimately found guilty and the penalties amounted to as much as £9300 The offence was clearly that of fraud against the excise, there was no question of this trick having any prejudicial influence upon health The following cases however illustrate the utter indifference of some persons as to whether or not they poison the public. A farmer and dairyman from Exeter was fined at the Guildhall Police-court £20, with £4 4*s* costs, for sending to the Central Meat Market, London, the carcasses of two pigs which were diseased and unfit for human food. Again, a dealer from Leicestershire was summoned at the Guildhall for being the owner of certain diseased meat that was deposited in the Central Meat Market for the purpose of sale. The carcasses all showed signs of a wasting disease. The fine in this case was £100 and the costs were £3 3*s* In another instance a firm of shopkeepers in Regent-street, London, were summoned for selling cocoa containing 40 per cent. of sugar, 27 per cent. of starch, and 0 15 per cent. of red oxide of iron. The defendants were fined £3, with 12*s* 6*d* costs. It is evident that the heinousness of an offence is not represented by the amount of a fine, for surely a fraud calculated to cause injury to health is of a worse description than a fraud which cheats the excise. Yet in the latter instance the fine is generally enormous, and in the former it is, comparatively speaking, microscopic Morally the offence which is calculated to prejudice health is greater than the offence against the excise laws of the country Legally, however, it is obviously not so In short, the fines inflicted on persons who knowingly send diseased meat for sale into the market are altogether inadequate.

INSTANCES OF EXTREME OLD AGE

THE *Daily Chronicle* reports "the Royal College of Surgeons —a synonym in this case for the whole of the medical profession—as "mightily concerned" with what the Russian newspapers are supposed to have published regarding an alleged "bi-centenarian" now lying bedridden in a hospital at Tomsk. John Hunter might have sent an emissary to report on this reputed marvel—indeed, he once despatched a man on a Polar expedition—but the College does not encourage such quests as these at present It is not probable that a greatly moved College is sending officially for the old man's papers, though of course it would not refuse his likeness or any properly authenticated account of him. The difficulty is to prove the authenticity of centenarians' claims. The Methuselah of Tomsk bases his on an ancient passport, dated 1763, in which someone is described as being aged 60 in that year Supposing such a paper to exist it would only prove that a man of the same name as the bi centenarian was alive in 1763 Peasants or small farmers, to which class this old man belongs, have often accumulations of ancient papers and, when not illiterate, often sign the same Christian names from father to son for centuries A portrait of the old man would not help us either, it would only prove him to be looking very old The interest in centenarians is always great and indeed to some people fascinating As recently as 1878 a certain Michael Solis, of semi-Spanish origin, resided in Bogota, Colombia, and was alleged to be 184 years old.[1] *La Epoca*, a New Granada journal, wrote at the time of one Miguel Lollo, whom we take to be identical with Michael Solis —"The signature of this venerable *anciano* [ancient] is affixed to a deed relating to the foundation of a convent, and is dated 1712. Dr. Hernandez who had heard about this Miguel Lollo, was desirous of making his acquaintance and found him busy gardening His skin is like parchment, and his hair as white as snow It militates against the genuineness of both Michael Solis and the old man of Tomsk that during the last 60 years or so previous to what we may describe as their discovery no one had ever seen or heard of them. They are apparently unknown to such well known writers on centenarians as Easton of Salisbury and Sharon Turner Mr Redding Ware, who mentions Lollo with caution in 1885, knows nothing of the Tomsk man Surely a bicentenarian should have been famous for years, as was Henry Jenkins, the old English peasant who died in 1670 but had been visited by various witnesses from 1650 onwards. Moreover, Jenkins had specific recollections, such as that of taking a horse load of arrows in the direction of Flodden Field in 1513, whereas the Russian peasant above discussed seems only to refer vaguely to remote persons and events

A MEDICAL OFFICER IN ANCIENT GREECE

AN ancient inscription more than 2000 years old has recently been discovered at Amphissa in Greece which is particularly interesting to all members of the medical profession. It is a decree of thanks to a doctor honouring him for his good works, and being practically complete is probably one of the oldest documents containing an eulogium of a medical man in existence We give the text complete as it speaks for itself, adding only a few words of commentary further to elucidate its meaning The text itself and most of the supplementary remarks are derived from an essay upon the inscription by M. Wilhelm Vollgraff[1]

To propitious fortune

The Archons and the city of the Amphissians to the Archons and to the city of the Scarphians greeting We have forwarded to your town a copy of the decree engrossed by our city in honor of the doctor Menophantos son of Artemidorus a Macedonian of Hyrcania as Menophantos has requested us to do

In the month of Amon the day Proposition of the nonarchs Take *notice that Menophantos son of* Artemidorus Macedonian *of* Hyrcania doctor having been invited by our city has established himself therein and has on his sole account accepted the responsibility *of the medical duties* Behold when *most serious* diseases *manifested* themselves he ably cared for us and next to the gods it is to him thanks to his exertions and personal energy that our attacked citizens were rescued

Take notice he has been attested as irreproachable for having lavished his cares upon all without distinction with constant honesty and perfect equality and for having watched over all things (or cases) with benevolence.

Take notice that he has conducted himself during all the period of his sojourn among us with modesty and wisdom and has manifested a deportment of perfect dignity worthy of the city and his profession Also and moreover notwithstanding [his advanced] age and [accidents] which have befallen him he has acted in departing from our city

* * * * * * *

curing all the assembled sick and giving public consultations? [this rendering is doubtful] We grant Menophantos the Proxenia and give him permission We present to him because of his great attention and for his benevolence In order that there shall exist a visible monument of this Proxenia accorded to Menophantos we have forwarded a copy of this decree to the city of the Scarphians and we make the following proclamation The Amphissians have presented to Menophantos son of Artemidorus to him and to his descendants the Proxenia the right to acquire property the rights of pasturage protection in war time as in times of peace and all the other privileges which the laws grant equally to the other proxenies

It is not necessary here to set forth M Vollgraff s reasons for dating the inscription in the second century B C but they are sufficient. Scarphia, the city which for some reason the Amphissians and Menophantos desired should also exhibit a copy of this decree in honour of their medical resident, was close to Thermopylæ. It was but a short distance from Amphissa, which latter was close to Delphi. The medical man was evidently a descendent of some Macedonian who was a colonist of Hyrcania in Lydia, and who possibly emigrated there under Alexander or his successors, but as we are told that one of the Seleucid princes settled Macedonians in the Hyrcanian plain, which was in the Hermus Valley in the neighbourhood of Magnesia, his ancestors may be considered as coming from Macedonia at that time. The name of Menophantos is not a Macedonian one but evidently commences with the title of the deity Men who was a god of healing Many Greek medical men assumed names formed of compounds with the name Men, such as Menodotus, Menodoros, and Menophilos. Moreover, close to the Hyrcania from which Menophantos came, Strabo tells us there was a temple of the god Men and at this sanctuary there was a school of medicine. It is quite possible this school existed in the youth of Menophantos and that he studied there. There are some 20 honorary decrees, or notices, of medical men in the various collections of ancient inscriptions, showing that the members of the profession were in many cases worthy citizens and virtuous and kindly men and, further, that their efforts for the amelioration of the bodily ailments of their fellow creatures were fully appreciated. Two of these texts may be found in Newton's "Greek Inscriptions in the British Museum," vol ii., pp 143 and 258, and others in Messrs. Paton and Hicks's "Inscriptions of Cos," Nos 5 and 344

THE NATURE OF A JELLY

IT is a remarkable fact that water may be made to assume apparently the solid form by adding 1 per cent. only of gelatin to it. The more or less stiff jellies used as table delicacies contain probably over 95 per cent of water The jelly fish similarly contains only a small percentage of solid matter This remarkable property of gelatin of rendering water, so to speak, solid has been a problem to physicists. It is generally maintained, however that after all the water in a jelly is in a fluid condition and that therefore it retains its properties unchanged. According to this view the solid condition of a jelly is a property of the gelatin itself At any rate it has been established that a jelly behaves under certain physical experiments very little differently from water Thus jelly offers little more resistance to the passage of diffusing substances than does pure water The condition of water in a jelly, therefore, resembles its state when absorbed by a highly porous substance such as pumice stone or sponge. In other words, the gelatin on setting forms a sort of fine spongy network in which the liquid water is held captive by capillary forces Gelatin is, in short, a very capacious carrier of water, and it is not unreasonable to suggest that in those cases in which the conveyance of some liquids is found to be inconvenient the use of gelatin might afford an easy way out of the difficulty Thus, by dissolving a very little gelatin in milk the milk could be carried in solid blocks Moreover, the milk would gain rather than lose nutrient value by the process

THE HOSPITAL PROBLEM IN LONDON

A MEETING of the Hospitals Association was held at Caxton Hall, Westminster, on March 3rd, when a full attendance was present to hear an address by Sir Henry Burdett entitled, "The Hospital Sites and Population in London" Sir Henry Burdett discussed in an interesting and practical way the problem as to whether any, and if so which, of the large hospitals ought to be moved from their present sites to new ones situated in less congested districts or, alternatively, into the country He gave figures to show that the accepted ideas with regard to the ratio of general hospital beds to population was very far from accurate It is common to speak of the deplorably inadequate supply of hospital accommodation, but Sir Henry Burdett showed that the population within the whole of the postal district of London was, in his opinion, well supplied with general hospital beds, although certain districts were not so fortunate. Among many pregnant suggestions, he alluded to the possibility of certain amalgamations of existing hospitals as being likely to result in a more uniform supply of hospital accommodation in different districts. Mr Sydney Holland pointed out that one difficulty of procuring the combination of hospitals would be the objection raised by the medical staffs, and other speakers alluded to different manifest objections to the transporting of hospitals from their original sites. Various speakers touched upon the powers and duties of the London County Council and the London Boroughs in respect of municipalising hospitals, and Sir Edmund Hay Currie probably expressed the feeling of most of us who have deliberated over this difficult question when he said that the transplantation of ancient charities must be approached in the most gentle manner possible. The address and subsequent speeches formed an interesting contribution to one of the most urgent questions of modern London sociology, and we hope in a later issue to give a fuller report of the meeting and to comment upon some of the suggestions that were made.

---

[1] Bulletin de Correspondance Hellenique 1901 pp. 234-240.

THE PREVALENCE OF SMALL-POX

CASES of small pox continue to occur at various places in the north of England. Thus 2 cases have occurred in Altrincham and 5 cases from Dunham Massey are under treatment in the isolation hospital at Baguley In addition we regret to state that Mr T W H. Garstang, the medical officer of health of the Bucklow Union, has been attacked by the disease, but fortunately in a very mild form. At Wrexham 3 cases have recently been notified, while at Liverpool 105 cases had occurred in the week ending Feb. 27th, as against 54 in the previous week. Swansea, it will be seen in the letter from our Welsh correspondent, which appears at p. 689, has been free from small pox for some weeks. The Local Government Board for Scotland intimate that during the period from Feb. 15th to 28th inclusive one case only of small pox has been notified to them—viz., the case of a fireman on board a ship which arrived at Glasgow on Feb 8th.

HYDATID CYST OF THE HEART RUPTURE INTO THE LEFT AURICLE

IN the *Intercolonial Journal of Australasia* of Dec. 20th, 1902, Dr C A. Altmann has published a rare case of hydatid disease. A servant girl, whilst gathering chips to light a fire, suddenly fell down in a fit. In about ten minutes she was seen by Dr Altmann who found her dead. She had been apparently in good health except for a slight headache on the previous day About three weeks previously her life had been insured as a first-class one. The necropsy showed that the posterior wall of the left auricle was occupied by a hydatid cyst, of about the size of an orange when full, which had ruptured into the auricle The heart was enlarged and with the empty cyst weighed 13 ounces The left external carotid artery was blocked by a daughter cyst at its point of entrance into the cranium. Permission could not be obtained for making a thorough dissection of the vessels of the neck.

HYGIENE FOR OUR GIRLS

A WORK on the subject of personal hygiene for women emanating from a French source and written by a French woman could hardly be expected to be taken seriously in this country at least, where considerations of personal hygiene for women and children present fewer features of novelty The reader however, who takes up Madame Augusta Moll-Weiss's little book of advice for "The Mothers of To-morrow,"[1] with the expectation of deriving amusement or of finding material for superior criticism will be infinitely disappointed, for not only is the subject matter handled in a thoroughly sound and scientific manner, but such delicate subjects as come under review are treated with so much appreciation of modesty that it would be difficult for a translator to find an equivalent *finesse* of expression in the English rendering When the author takes up her parable it is to preach the gospel of plain living and high thinking, cold water baths, hygienic costuming, and muscular exercise, and on what better text would it be possible to enlarge? The programme for physical recreation appears, however, lamentably uninteresting and limited in comparison with the possibilities which are open to girls in this country for healthy exercise There are certain points touched upon in Madame Moll-Weiss's little book in respect of which those of our countrywomen who are interested in "l'éducation de la jeune fille d'après sa physiologie" may certainly study with advantage, and not the least of these is the question of appropriate dressing The words of advice which Madame Moll Weiss has to offer on this subject are so strictly sensible, hygienic, and practical that we imagine that they will appeal not only to "les mères de demain" for whose benefit they are written, but even to the "*mere male*" who takes up this little book out of curiosity The young women of to-day will perhaps hardly sympathise with, or indeed believe in, the statement that "le vêtement est fait pour le corps et non le corps pour le vêtement."

SIR ERNEST CASSEL'S GIFT FOR THE RELIEF OF OPHTHALMIA IN EGYPT

THE recent generous gift of £40,000 intrusted to Lord Cromer and his successors in office by Sir Ernest Cassel for the relief of ophthalmia and diseases of the eye and for the training of qualified men for such work in Egypt was the direct outcome of the Khedive expressing interest in the subject. The Khedive saw the proposal for an ophthalmic research hospital which had been submitted by Mr Kenneth Scott of London in the hope that the funds required for starting it might be provided The officials of the Sanitary Department of the Egyptian Government, into whose hands the expenditure of the sum has virtually passed, have decided to employ it in establishing a tent in the form of a "travelling dispensary," to suffice for all purposes of operation and treatment and to work solely in the provinces. They will appoint an additional English inspector for a temporary period to travel with it, accompanied by a native Egyptian medical man, a post-graduate local medical student, two male hospital attendants and two servants. Beyond the initial cost of about £250, its annual maintenance, inclusive of salaries, is estimated at £900

THE QUESTION OF FORECASTING LONDON FOGS

WE mentioned in an annotation in THE LANCET of Oct 26th, 1901, p 1139, that electric and gas lighting companies had approached the Meteorological Office upon the question as to whether a system could be established by which special forecasts or warnings of the onset of fogs could be issued. Subsequently the Meteorological Office communicated with the London County Council upon the subject with the result that the General Purposes Committee practically agreed to coöperate with the Meteorological Office in setting on foot an inquiry into the conditions of formation of fog in and around London, and £250 were voted for the purpose. The report has recently been laid before the council and although some interesting observations have been made the results on the whole are, it must be confessed, disappointing It was ascertained that elevated stations are less visited by fogs than other stations, but the real locality of fog at any particular time would appear to depend upon local atmospheric conditions. The beginning of a fog is a widespread process depending upon general atmospheric conditions. It does not appear that fogs which form outside drift into London. That is practically all that the inquiry has shown, but it is pointed out that a regular system of observations of temperature might indicate the possibility of predicting fogs locally The report certainly suggests further investigation upon certain points, but the London County Council decided at its last meeting not for the present to centenarians as Easton of Salisbury and Sharon Turner Mr Redding Ware, who mentions Lollo with caution in 1885, knows nothing of the Tomsk man Surely a bi centenarian should have been famous for years, as was Henry Jenkins, the old English peasant who died in 1670 but had been visited by various witnesses from 1650 onwards Moreover, Jenkins had specific recollections, such as that of taking a horse load of arrows in the direction of Flodden Field in 1513, whereas the Russian peasant above discussed seems only to refer vaguely to remote persons and events

A MEDICAL OFFICER IN ANCIENT GREECE

AN ancient inscription more than 2000 years old has recently been discovered at Amphissa in Greece which is particularly interesting to all members of the medical profession. It is a decree of thanks to a doctor honouring him for his good works, and being practically complete is probably one of the oldest documents containing an eulogium of a medical man in existence We give the text complete as it speaks for itself, adding only a few words of commentary further to elucidate its meaning The text itself and most of the supplementary remarks are derived from an essay upon the inscription by M Wilhelm Vollgraff [1]

To propitious fortune

The Archons and the city of the Amphissians to the Archons and to the city of the Scarphians greeting We have forwarded to your town a copy of the decree engrossed by our city in honor of the doctor Menophantos son of Artemidorus a Macedonian of Hyrcania as Menophantos has requested us to do

In the month of Amon the day Proposition of the nonarchs Take *notice that Menophantos son of Artemidorus Macedonian of* Hyrcania, doctor having been invited by our city has established himself therein and has on his sole account accepted the responsibility of the medical duties Behold when most serious diseases manifested themselves he ably cared for us and next to the gods it is to him thanks *to his* exertions and personal energy that our attacked citizens were rescued

Take notice he has been attested as irreproachable for having lavished his cares upon all without distinction with constant honesty and perfect equality, and for having watched over all things (or cases) with benevolence.

Take notice that he has conducted himself during all the period of his sojourn among us with modesty and wisdom and has manifested a deportment of perfect dignity worthy of the city and his profession Also and moreover notwithstanding [his advanced] age and [accidents] which have befallen him he has acted in departing from our city

* * * * * * *

curing all the assembled sick and giving public consultations? [this rendering is doubtful] We grant Menophantos the Proxenia and give him permission We present to him because of his great attention and for his benevolence In order that there shall exist a visible monument of this Proxenia accorded to Menophantos we have forwarded a copy of this decree to the city of the Scarphians and we make the following proclamation The Amphissians have presented *to Menophantos, son of Artemidorus to him and to his descendants* the Proxenia the right to acquire property the rights of pasturage protection in war time as in times of peace and all the other privileges which the laws grant equally to the other proxenies

It is not necessary here to set forth M Vollgraff's reasons for dating the inscription in the second century B C but they are sufficient. Scarphia, the city which for some reason the Amphissians and Menophantos desired should also exhibit a copy of this decree in honour of their medical resident, was close to Thermopylæ It was but a short distance from Amphissa, which latter was close to Delphi. The medical man was evidently a descendent of some Macedonian who was a colonist of Hyrcania in Lydia, and who possibly emigrated there under Alexander or his successors, but as we are told that one of the Seleucid princes settled Macedonians in the Hyrcanian plain, which was in the Hermus Valley in the neighbourhood of Magnesia, his ancestors may be considered as coming from Macedonia at that time The name of Menophantos is not a Macedonian one but evidently commences with the title of the deity Men who was a god of healing Many Greek medical men assumed names formed of compounds with the name Men, such as Menodotus, Menodoros, and Menophilos. Moreover, close to the Hyrcania from which Menophantos came, Strabo tells us there was a temple of the god Men and at this sanctuary there was a school of medicine. It is quite possible this school existed in the youth of Menophantos and that he studied there. There are some 20 honorary decrees or notices, of men in the various collections of ancient inscriptions, ing that the members of the profession were in many worthy citizens and virtuous and kindly men and, that their efforts for the amelioration of the bodily of their fellow creatures were fully appreciated Two these texts may be found in Newton's "Greek Inscriptions the British Museum," vol. ii., pp 143 and 258, and others in Messrs Paton and Hicks's "Inscriptions of Cos," Nos 5 and 344

THE NATURE OF A JELLY

IT is a remarkable fact that water may be made to apparently the solid form by adding 1 per cent. only of gel to it. The more or less stiff jellies used as table delicacies contain probably over 95 per cent of water The jelly fish similarly contains only a small percentage of solid matter This remarkable property of gelatin of rendering water, so to speak, solid has been a problem to physicists It is generally maintained, however that after all the water in a jelly is in a fluid condition and that therefore it retains its properties unchanged. According to this view the solid condition of a jelly is a property of the gelatin itself. At any rate it has been established that a jelly behaves under certain physical experiments very little differently from water Thus jelly offers little more resistance to the passage of diffusing substances than does pure water The condition of water in a jelly, therefore, resembles its state when absorbed by a highly porous substance such as pumice stone or sponge. In other words, the gelatin on setting forms a sort of fine spongy network in which the liquid water is held captive by capillary forces Gelatin is, in short, a very capacious carrier of water, and it is not unreasonable to suggest that in those cases in which the conveyance of some liquids is found to be inconvenient the use of gelatin might afford an easy way out of the difficulty Thus, by dissolving a very little gelatin in milk the milk could be carried in solid blocks. Moreover, the milk would gain rather than lose nutrient value by the process

THE HOSPITAL PROBLEM IN LONDON

A MEETING of the Hospitals Association was held at Caxton Hall, Westminster, on March 3rd, when a full attendance was present to hear an address by Sir Henry Burdett entitled, 'The Hospital Sites and Population in London." Sir Henry Burdett discussed in an interesting and practical way the problem as to whether any, and if so which, of the large hospitals ought to be moved from their present sites to new ones situated in less congested districts or, alternatively, into the country He gave figures to show that the accepted ideas with regard to the ratio of general hospital beds to population was very far from accurate It is common to speak of the deplorably inadequate supply of hospital accommodation, but Sir Henry Burdett showed that the population within the whole of the postal district of London was, in his opinion, well supplied with general hospital beds, although certain districts were not so fortunate. Among many pregnant suggestions, he alluded to the possibility of certain amalgamations of existing hospitals as being likely to result in a more uniform supply of hospital accommodation in different districts. Mr Sydney Holland pointed out that one difficulty of procuring the combination of hospitals would be the objection raised by the medical staffs, and other speakers alluded to different manifest objections to the transporting of hospitals from their original sites. Various speakers touched upon the powers and duties of the London County Council and the London Boroughs in respect of municipalising hospitals, and Sir Edmund Hay Currie probably

THE SUPPLY OF MIDWIVES.

A CONFERENCE convened by Mrs. Heywood Johnstone was held at the Grosvenor crescent Club, Hyde Park Corner London, on March 3rd, under the chairmanship of Sir MICHAEL FOSTER, K.C.B., to discuss schemes for the supply of midwives to the rural and provincial poor in accordance with the Midwives Act of 1902.

Sir MICHAEL FOSTER said that those who supported that Bill were largely influenced by the consideration that at the present time the supply of trained midwives was not adequate for the wants of the poor. They must act promptly and efficiently, so that by the time the Midwives Bill became a compulsory measure there would be a sufficient number of trained midwives. The truly representative character of the meeting that they were holding was shown by the fact that they had present amongst them representatives from no less than 26 counties of England.

Mrs. HEYWOOD JOHNSTONE said that as a result of her inquiries into the provision of midwives and maternity nurses for the poor throughout England and Wales it appeared that if the untrained midwife was suppressed and no one was put in her place in many districts the condition of affairs would be much worse than it had been. The speaker then entered into the details of the statistics she had compiled and mentioned that in Leicester, for a population of 212,000 only two trained midwives were to be discovered. In Cardiff, with a population of 65,000, there was a great need for properly trained women, and the result of the want of them had been in every way most disastrous. In country districts the want was more serious; in Dorset, for instance, a certain locality containing many scattered villages afforded for the attendance of all the cases one old woman, 88 years of age, and the villagers said that when she died they did not know what they would do. On inquiry from the local medical man a verification was obtained of these facts. Mrs. Johnstone's object was to discuss a plan which would not involve large outlay. She considered that every parish should start an association for the supply of trained midwives and maternity nurses. Labourers should subscribe a small sum and the big houses in the neighbourhood should subscribe a guinea; very small parishes should combine. A great point was that such associations should be self supporting. To start these associations a very moderate outlay was sufficient—in fact, a few shillings from all who know the luxury of good nursing would be enough.

Dr. ROBERT BOXALL said that the object of the meeting was to provide for the wants of the rural districts; the needs of those in towns were generally well known and provided for but the necessities of the country districts were not so fully appreciated. Unless the needs of their poorer sisters were put forward by those who knew the conditions there was a chance that their claims might be ignored. The question was how to secure competent and skilled assistance in rural districts. Dr. Boxall gave a description of the conditions prevailing in the Scilly Islands, in the rural districts of Sussex, and in Sutherlandshire. It was in the country that the necessity for the midwives was mostly felt, where locomotion was slow and time in complicated cases was an important matter. In those districts the midwife would be welcomed by the medical man. The fact was, however, that of the midwives who were trained the majority only intended to work as nurses under medical men. It was very rarely indeed that a midwife could be induced to take up work in country districts. A selection might be made from among the women in the country practising midwifery without training, and the problem which called for solution was how to provide these people with a proper training.

Mrs. RICKMAN said that the class of woman they wanted for midwives was unable to pay for the necessary training. She advised taking married women in the villages to be trained and then guaranteeing them a sufficient sum so that they could do the work. These women could not move away from the district and would therefore be available.

Mrs. SOWDON of Hackney detailed to the meeting how the poor people in her neighbourhood maintained a self supporting association for the supply of midwives.

Nurse GREGORY, from the Winchester Lying in Charity, explained the principle adopted at Winchester of sending out pupil nurses with the midwives, so that they should learn village work and make themselves of use in the cottages when the mother was confined.

Mr. HEYWOOD JOHNSTONE, M.P., said that the Midwives Act of 1902 would not be a blessing but the reverse if the large number of women who preferred to be attended by their own sex were deprived of the assistance of untrained women and no one else was supplied to take their place. He considered that Mrs. Rickman's suggestion to train suitable women in small country villages was very helpful. He thought they should particularly emphasise the point that if the training of midwives was made too protracted the supply would be limited. Limitation would also occur if the training unfitted the women for cottage life. He concluded by moving a motion to the effect that it was desirable to form an association to carry into operation suitable plans for the supply of midwives to the rural and provincial poor.

Lady CAMOYS seconded the motion, which was put to the meeting and declared carried with one dissentient.

Lord CAMOYS, in moving a vote of thanks to the chairman, urged that too high a standard of efficiency to begin with should not be demanded of the midwives.—The vote was seconded by Mrs. HEYWOOD JOHNSTONE and duly carried and acknowledged by the Sir MICHAEL FOSTER.

Before the meeting closed Mr. F. R. HUMPHREYS asked those present to urge on the attention of Poor law guardians the advisability of removing the technical difficulties in the way of training being afforded to midwives at the Poor law infirmaries.

THE IRISH DISPENSARY MEDICAL OFFICER.

THERE is, we think, no department of the profession in such a deplorable condition at present as the Poor law medical service in Ireland; and, notwithstanding the praiseworthy efforts of various organisations—and notably the Irish Medical Association—the state of that service shows little sign of improvement. It is a common jibe to throw at Irishmen that they are never without a grievance, but even admitting that there may be, perhaps, at times some truth in such an accusation we believe that no one will deny after reading our article that the dispensary medical officers of Ireland have just grounds of complaint.

Grievances of Irish Dispensary Medical Officers.

1. There is no promotion in the Irish Poor law medical service. 2. The salary is totally inadequate. The average annual salary of a dispensary medical officer in Ireland varies from about £100 to £150. He has charge of a district from ten to 20 miles in area and he has often in a day to travel 40 miles, so that when he deducts from his salary the cost of his horse (and one is often not enough to work his district) and car and man servant he has literally and practically no pay at all; and yet he is always on duty and must be prepared at any time of the day or night to operate for strangulated hernia, to deal with a placenta prævia, or to treat a complicated case of typhoid fever. 3. He has no holiday as of right. We admit that the Local Government Board authorised the boards of guardians to give their dispensary medical officers a month's vacation but unfortunately it made it *permissive*, not *mandatory*, and there are so much trouble in fixing the salary of a locum tenent, such an amount of red tape in nominating a substitute and finally, so much difficulty in procuring one at the poor pay so frequently offered, that in the end many a jaded dispensary medical officer is obliged to do without any holiday at all—an arrangement which, in the interests of the poor, is a very bad one. 4. There is no increase in salary, for neither length of service nor efficiency in the discharge of duty brings the slightest pecuniary reward. 5. There is no pension guaranteed as a right, as in civil service. The result is that it is too often the case that men rendered inefficient by age and hard work are obliged, in order to live and to keep out of the workhouse, to continue far too long at duty until, as in one notable example, after a service of 40 years, a dispensary medical officer died from exhaustion on the roadside worn out by advancing years and continuous strain of body and mind.

Causes of the Present Deplorable Position of Irish Dispensary Medical Officers.

1. There can be no doubt that the most potent cause of the great dissatisfaction existing at present amongst Irish

vote any further sum of money towards a continued prosecution of the subject. We come back thus to a conclusion, long ago arrived at by ourselves, that it is impossible to prevent the formation of fog but that it is possible to prevent its defilement with soot, as the Coal Smoke Abatement Society has shown.

ST BARTHOLOMEW'S HOSPITAL

THE committee which was formed, as we announced in THE LANCET of Jan 24th, p 254, for the purpose of inquiring into various matters concerning St. Bartholomew's Hospital has decided at least one point of the *terms* of reference—namely that the hospital shall remain upon its present site. This decision was arrived at by 14 votes to one Sub-committees have been appointed to inquire into the question of cost and other matters. We learn that it is not intended to enlarge the hospital but to make such alterations as shall bring the hospital buildings into accord with modern ideas. The determination to remain upon the existing site is, we think, a just and right one We have already[1] given our reasons for thinking that the present site should be retained, while at the same time we pointed out the difficulties in the way of such a decision. We need not repeat what we have said upon this matter, but we await with interest the reports of the sub-committees which have been appointed to consider the financial side of the question

THE DISTRIBUTION OF PLAGUE

As regards the Mauritius a telegram from the Governor received at the Colonial Office on Feb 27th states that for the week ending Feb 26th there were 3 cases of bubonic plague and 1 death from the disease As regards the Cape Colony the medical officer of health of the colony states that for the week ending Feb 7th 2 cases of bubonic plague, both in male natives, were discovered at Port Elizabeth. The one case was admitted to hospital on Feb 4th and died on the 6th, the other case, admitted on Feb 6th, remained in hospital at the date of the statement, Feb 9th, being the only case in the plague hospital at the end of the week under review No case of plague had occurred at any other place in the colony, but rats were reported from Graaf Reinet on Jan. 31st to be dying in a suspicious manner An investigation was made and the disease from which the rats were suffering was found to be plague As regards Hong Kong a telegram from the Governor received at the Colonial Office on March 3rd states that for the week ending Feb 28th there were 12 cases of plague and 12 deaths from the disease. As regards Egypt no cases of, or deaths from, plague have occurred during the week ending Feb 22nd.

THE CARDIFF AND COUNTY PUBLIC HEALTH LABORATORY

THE third annual report of the bacteriologist of the above laboratory, Dr William G Savage, illustrates again the usefulness and importance of such an institution and we hope in the interests of public health that municipal laboratories will be the rule before long throughout the country This hope is amply justified by the following examples of the work carried out in the Cardiff and County Public Health Laboratory Many waters from suspected supplies and proposed new sources have been investigated Data of value for determining the purity of water supplies were thus obtained which proved of much practical utility in enabling opinions to be *formed* as to the purity of any given supply Moreover, samples of food have been bacteriologically examined and as a result a large proportion of the samples of diseased meat found to be from animals suffering from tuberculosis half the samples of so-called sterilised milk proved contain organisms. A large number of specimens sent in medical men were examined during the year and as pointed out the identification of doubtful cases of typhoid fever, and other diseases is very greatly aided bacteriological examination Other work done in the tory has dealt with methods of disinfection, the tion of vermin, and the condition of sewage effluents waste waters discharged into streams from industrial works

HORSED AMBULANCES FOR LONDON

WE are glad to learn that the London County Council considering in committee the formation of a service of ambulances for London Such ambulances have existed Liverpool for some 20 years, while Blackpool, and Wolverhampton also possess them. The ambulances, ho ever, do not belong to the aforesaid municipalities but to local hospitals. Here in London we have neither munic nor, we think, hospital horsed ambulances, excluding possessed by the Metropolitan Asylums Board. The Amb Corps of the Order of St. John of Jerusalem possesses some, but these, so far as we know, are the only horsed ambulance available in the case of a street accident The very horses of the two great omnibus companies are in better case is the casual citizen, for these hard working and animals are conveyed home in an ambulance should fall in the street, provided that they are not so badly that the merciful bullet has to be called into requisition Every surgeon on the staff of a London hospital, and most house surgeons, can recall cases of street accidents where injuries have been gravely increased by the methods of conveying the patients to the hospital. The surest way of rendering a simple fracture of the leg compound is by crowding the patient into a hansom, yet this is not uncommonly the course pursued by the good Samaritan who assists at a street accident It is proposed, we believe, that the ambulance service should be in connexion with the fire brigade If this means throwing extra duties upon the fire brigade we hope that this part of the scheme will fall through and, moreover, we trust that a special ambulance stud will be provided, for a fire-engine horse is not the most fitting motive power for conveying a case of severe accident to the hospital, although the fire-engine horses are used for the purpose in some cities

Mr Thomas Wilson, M.D Lond, F R C S. Eng, who has held the office of assistant obstetric officer at the General Hospital, Birmingham, for the past ten years, has been unanimously elected honorary obstetric officer in place of Dr Edward Malins, the President of the Obstetrical Society of London, who has resigned that post

A CONVERSAZIONE will be given at the West London Hospital by the Post-graduate College on Wednesday, March 18th, at 8.30 P M All past residents and past and present post-graduates are invited to be present.

WE are asked to announce that the meeting of the Medical Society of London on March 23rd will be a "clinical evening" and that the papers on Diseases of Children set down for that date are unavoidably postponed.

THE existing Vaccination Act is to be renewed for one year, further legislation on the subject being deferred until a future session.

---

[1] THE LANCET Jan 17th 1903 p 180.

excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9 3 in Perth and 10 5 in Leith to 18 8 in Glasgow and 22 0 in Aberdeen. The 581 deaths in these towns last week included 23 which were referred to whooping-cough, 13 to diarrhœa, nine to measles, six to diphtheria five to scarlet fever, two to "fever," and one to small-pox. In all, 59 deaths resulted from these principal infectious diseases last week, against 80, 85, and 76 in the three preceding weeks. These 59 deaths were equal to an annual rate of 1 8 per 1000, which was 0 2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 32 and 26 in the two preceding weeks, further declined last week to 23, of which 16 occurred in Glasgow, three in Edinburgh, and two in Dundee. The deaths from diarrhœa, which had been 16 and 18 in the two preceding weeks, declined again to 13 last week, and included six in Glasgow, three in Dundee, and two in Aberdeen The fatal cases of measles, which had declined from 20 to 12 in the four preceding weeks, further decreased last week to nine, of which four were registered in Aberdeen and four in Leith. The deaths from diphtheria, which had been three and five in the two preceding weeks, further rose to six last week, and included two in Glasgow and two in Aberdeen. The fatal cases of scarlet fever, which had been eight and seven in the two preceding weeks, declined again last week to five, of which two occurred in Paisley The two deaths from "fever" and the fatal case of small pox were registered in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 134, 112, and 109 in the three preceding weeks, further declined last week to 92, and were 122 below the number in the corresponding period of last year The causes of 20, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 26 4 25 0, and 20 6 per 1000 in the three preceding weeks, rose again to 25 9 per 1000 during the week ending Feb 28th During the past four weeks the death rate has averaged 24 5 per 1000, the rates during the same period being 17 1 in London and 15 9 in Edinburgh. The 188 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 38 over the number in the preceding week, and included 14 which were referred to the principal infectious diseases, against nine, 14, and 18 in the three preceding weeks, of these five resulted from whooping-cough, four from diarrhœa, two from scarlet fever one from measles, one from diphtheria, and one from "fever" These 14 deaths were equal to an annual rate of 1 9 per 1000, the death rates last week from the same diseases being 1 7 in London and 1 1 in Edinburgh. The fatal cases of whooping cough, which had been three in each of the three preceding weeks, rose last week to five. The deaths from diarrhœa, which had been four and one in the two preceding weeks, rose again to four last week. The fatal cases of scarlet fever, which had been two three, and four in the three preceding weeks, declined again last week to two The 188 deaths in Dublin last week included 31 of children under one year of age and 47 of persons aged 60 years and upwards, the deaths both of infants and of elderly persons showed an excess of 10 over the respective numbers recorded in the preceding week. Seven inquest cases and seven deaths from violence were registered, and 65 or more than a third, of the deaths occurred in public institutions The causes of 12, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES

Royal Navy Medical Service.

The following appointments are notified —Staff Surgeons A. Cropley to the *Pembroke* to be lent to the *Mersey*, W G Axford to the *Duke of Wellington*, for Haslar Hospital temporary Surgeons B Ley to the *Spartiate*, for medical charge on voyage out, and to the *Algerine* undated. Robert Robertson Fasson has been appointed medical officer at Keyham Dockyard, Devonport.

The undermentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in His Majesty's Fleet — Timothy Joseph Crowley, Donald Templeton Hoskyn, Robert Howard Nicholson, and John Leslie Barrington.

Royal Army Medical Corps.

Major W T Mould, on arrival at Southampton, in relief of Captain E W Slayter, takes over the duties of Embarking Medical Officer Colonel J C Harwood is appointed to the medical charge of the Station Hospital, Poona Lieutenant-Colonel W G Birrel is appointed to the medical charge of the Station Hospital, Colaba, and Major J R Stuart to the medical charge of the Station Hospital, Aden Captain A L. Webb is posted to the Poona District and Captain J Matthews to the Deesa District Lieutenant-Colonel W O Wolseley is posted to Edinburgh Castle for duty Major G F Moffet assumes medical charge of the troops, Station Hospital, &c., Maryhill, Glasgow Major G Scott assumes medical charge of the troops, Station Hospital, Fort George, vice Major D Stiell, who is under orders for India. Major H M Sloggett has arrived at Dover for duty, and is posted to the Station Hospital, Dover Castle. Major A P H. Griffiths is transferred from the Deesa to the Aden District, and Lieutenant F M Parry from the Bombay to the Nagpur District.

Volunteer Corps.

Royal Garrison Artillery (Volunteers) 2nd Durham (Seaham) Surgeon Major L. G Dillon resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement. Dated March 4th, 1903.

Royal Engineers (Volunteers) 2nd Cheshire (Railway) Surgeon Captain J R. Atkinson resigns his commission Dated March 4th, 1903

Rifle 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment), Surgeon Lieutenant T F Devane to be Surgeon Captain. Dated Feb 17th, 1903. 1st Cadet Battalion the King's (Liverpool Regiment) Acting Surgeon W Evans resigns his appointment. Dated March 4th, 1903 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment Surgeon Lieutenant William Edward Manderson Corbett resigns his commission and is appointed Captain. Dated March 4th, 1903.

Correspondence.

Audi alteram partem."

THE TREATMENT OF INCIPIENT AND UNCONFIRMED MENTAL DISORDER

To the Editors of The Lancet

Sirs,—I trust that in view of the considerable interest I have taken in this matter you will grant me a portion of your valuable space. This subject was first raised in a discussion opened by me at the Carlisle meeting of the British Medical Association, when I proposed a motion (which was carried) recommending the council to support legislation in this direction. Subsequently, as chairman of a conjoint committee of the British Medical Association and Medico-Psychological Association, I had the honour of heading a deputation to the Lord Chancellor who thereafter adopted into his Lunacy Bill a clause drawn up by the conjoint committee. This clause provided for the treatment of such cases in private homes for six months without certification but with notification to the Commissioners in Lunacy This clause was passed by the House of Lords in two successive years and the matter appeared to have been so far settled Thus much of ancient history

It was therefore with some dismay and a feeling of "save me from my friends" that I listened to the recent paper of Sir William Gowers on this subject in which he again brought the matter under debate and advocated the accomplishment of what was almost a *fait accompli* Sir William Gowers I am sure, was unacquainted with the above facts or I am certain that with his usual high minded fairness and courtesy he would have mentioned the efforts of those who, like Dr E. W White, Dr T Outterson Wood, and myself and many others, had given no inconsiderable time and effort to obtain the above result.

At the Carlisle meeting I not only drew attention to the dispensary medical officers is the miserable remuneration which they receive for their services. Apart altogether from the increased expense of medical education, the cost of living is much higher now than it was many years ago , and, notwithstanding this fact, the salary of the dispensary medical officer in Ireland remains the same Further, owing to the gradual depletion of the country districts of Ireland of the former wealthy landlord class, and the tendency at present for dwellers in the rural districts to migrate into the cities, the dispensary medical officer has not now the same chance as formerly to supplement his miserable Poor law income by private practice. 2. The dual arrangement by which the dispensary medical officer is under the control of the Poor-law guardians and the Local Government Board does not work well. The disappearance of the *ex-officio* guardians (men of recognised social position and education) and the lowered status of the present elected guardians have made it almost impossible in many districts in Ireland for a medical man to work with any comfort or self respect He is in the hands of hard taskmasters who are ready on the slightest excuse to find fault with, or even to dismiss, him who have little sympathy with the professional classes, and whose chief aim is to keep down the rates The constant friction (no one looking at an Irish newspaper can fail any day to see examples) between these guardians and the Local Government Board arising from appeals—one day by the medical officers and the next day by the guardians—is daily increasing and is most vexatious

Means to Redress the Grievances of Irish Dispensary Medical Officers

If the Irish Poor law medical service can ever be improved it can only be done in one of two ways 1. Instead of the present method of appointment of dispensary medical officers (with all its political and sectarian intrigue) many people hold that it would be much better to select the dispensary medical officers by competitive examination and that in this way the present unsatisfactory method of canvassing for election would be done away with. 2 The only other plan for redressing the grievances of the Irish Poor law medical officers is for the rising generation of the medical profession in Ireland to combine and to refuse to offer themselves as candidates for any vacancies that may arise until the authorities, in the interests alike of the poor as well as of the profession, decide to improve the conditions of the service. So long as an Irish Chief Secretary (Mr Gerald Balfour) is able to say to a deputation from the Irish Medical Association—"How could they close their eyes to the fact that when one of these posts became vacant a large number of candidates presented themselves for it and the competition was very keen?"—it is useless to expect any reform. The members of the medical profession in Ireland must organise and combine and they have only to look for an example to the way the Army Medical Service was reformed when the War Office found that through the influence of the medical profession in the United Kingdom candidates would not apply for vacancies If the medical profession in Ireland will organise and combine in this way the authorities will quickly realise that the sooner the grievances of the dispensary medical officers in Ireland are redressed the better will it be for the public as well as the profession.

ASYLUM REPORTS

London County Asylum, Horton Manor, Epsom (Report for the year ended March 31st, 1902) —The average number of patients resident during the year was 724, comprising 110 males and 614 females. The admissions during the year amounted to 171—viz., seven males and 164 females. Of these 168 were first admissions Dr W Ireland Donaldson, the medical superintendent, states in his report that 51 patients among the admissions were transfers from other asylums, and that of the remainder about 42 per cent. were deemed irrecoverable. The number of patients discharged as recovered during the year amounted to 29, or 4 0 per cent. of the average number resident The deaths during the year amounted to 39 or 5 4 per cent. as calculated on the same basis Of the deaths one was due to colitis, six to general paralysis of the insane, six to pulmonary tuberculosis, and the rest to other causes. The general health of the institution was good, and the epidemic of influenza which occurred in February and March, 1902, was of a mild form. Three female patients admitted pregnant were safely delivered. The children were removed from the asylum to their respective unions. The Commissioners in Lunacy state in their report that the behaviour and personal condition of the patients were satisfactory that the wards and dormitories were in good condition, and that the medical case books were well kept. The committee of management states in its report that it has been decided to erect an additional block, similar to the existing buildings but separate therefrom, to accommodate 60 male patients. The cost of this block and its equipment is estimated at £9000 The expenditure on repairs of the asylum amounted to £4500, while the sum of £351 was spent on additions, alterations, and improvements

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8008 births and 4789 deaths were registered during the week ending Feb. 28th. The annual rate of mortality in these towns, which had been 17 9, 17 1, and 16 7 per 1000 in the three preceding weeks, further declined last week to 16 6 per 1000 In London the death rate was 16 3 per 1000, while it averaged 16 7 per 1000 in the 75 other large towns. The lowest death rates in these towns were 8 2 in Handsworth, 8 8 in Walthamstow, 9 3 in Hornsey, 9 3 in King's Norton, 10 4 in Reading, 10 9 in East Ham, 11 6 in Wallasey, and 11 7 in Leyton , the highest rates were 20 5 in Plymouth, 20 7 in Birkenhead and in Liverpool, 20 9 in Manchester and in Middlesbrough, 21 8 in Swansea 23 0 in Salford, 23 2 in Bury, and 24 3 in Wigan. The 4789 deaths in these towns last week included 452 which were referred to the principal infectious diseases against 512, 457, and 452 in the three preceding weeks , of these 452 deaths 108 resulted from whooping cough, 104 from measles, 81 from diphtheria, 55 from diarrhœa, 52 from scarlet fever, 35 from "fever" (principally enteric), and 17 from small pox. No death from any of these diseases was registered in Reading Handsworth, or Huddersfield , while they caused the lowest death rates in Brighton, Portsmouth, Leicester, Bolton, and Cardiff, and the highest rates in West Ham, Northampton, Hanley, Wigan, Bury, Manchester, and Oldham The greatest proportional mortality from measles occurred in Wigan, Manchester, Middlesbrough, and Swansea , from scarlet fever in West Bromwich, Bootle, St. Helens, and Oldham , from diphtheria in Northampton, Hanley, Coventry, and Bury , from whooping-cough in Hornsey, Northampton, Grimsby, and Preston, and from diarrhœa in West Ham. The mortality from "fever" showed no marked excess in any of the large towns Seven fatal cases of small pox were registered in Liverpool, four in Manchester, and one each in Aston Manor, Birkenhead, Bootle, Oldham, Burnley, and Preston The number of small pox cases under treatment in the Metropolitan Asylums hospitals, which had been six, six, and four in the three preceding weeks, had risen again to five at the end of last week , one new case were admitted during the week, against four, one, and seven in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday, Feb 28th, was 1851, against numbers declining from 2528 to 1893 on the nine preceding Saturdays , 197 new cases were admitted during last week, against 189, 246, and 205 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 315, 267, and 274 in the three preceding weeks, declined again last week to 271, and were 295 below the corrected average number The causes of 61, or 1 3 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol Bradford, Leeds, Sunderland, Cardiff, and in 43 other smaller towns, the largest proportions of uncertified deaths were registered in Liverpool, St. Helens, Blackburn, Barrow in Furness, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21 7, 18 1 and 18 1 per 1000 in the three preceding weeks, further declined to 17 7 per 1000 during the week ending Feb 28th, but was 1 1 per 1000 in miles east of Pretoria. No 3 Model School" was part of an *army* general hospital in which some of the medical officers and men of the Yeomanry Field Hospital and Bearer Company assisted for a time and did most excellent work. It was situated in the town of Pretoria.

I shall feel obliged if you would insert this explanation in justice to my colleagues on the staff of the Transvaal Imperial Yeomanry Hospitals (Pretoria, Elandsfontein, and Johannesburg)

I am, Sirs, yours faithfully,
C R. KILKELLY Surgeon Major, Grenadier Guards,
Late Principal Medical Officer Transvaal Imperial Yeomanry Hospitals.
Guards Depôt Caterham, Surrey Feb 19th 1903.

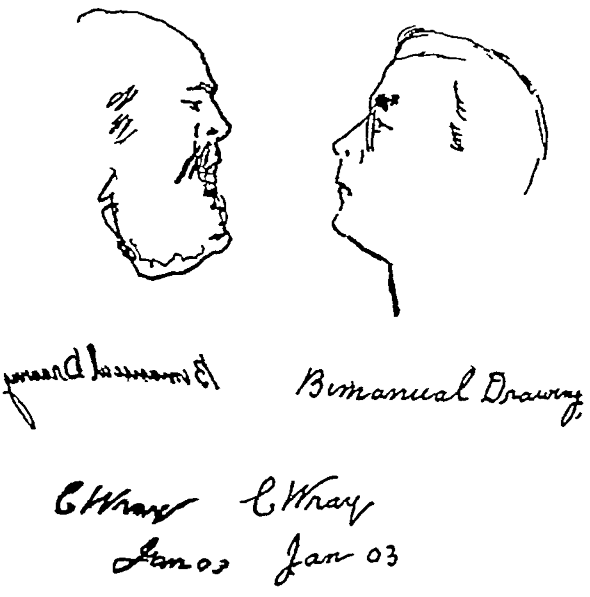
RIGHT-HANDEDNESS AND LEFT-BRAINEDNESS

To the Editors of THE LANCET

SIRS,—Left-handedness surely must not be taken as an indication of anatomical superiority of the right hemisphere of the cerebrum, for such superiority should result not only in left-handedness but in functional superiority of all the parts supplied and dominated by that half. Obviously, then, as a preliminary step it is necessary to ascertain the existence or non-existence of right- or left-footedness This your contributors do not seem to have done If left-footedness never exists then the theory of superior anatomical development of the right hemisphere falls to the ground and we may with comparative safety assume right-handedness as the result of training or unconscious imitation

I inclose drawings done with the right and left foot respectively, also several hand-drawings. None are touched up every stroke being in ink and final, the foot-drawings being done by means of a rough paper cone tied round the great toe. The drawing done by the left foot is, I think, equal to that done with the right. This is my second attempt at foot-drawing My impression is that I can control the left foot better than the right.

As regards the hands, I sharpen my pencils with the left hand and can handle a Graefe a shade better with it also In nothing else am I left-handed except in target shooting A perusal of the hand drawings shows no marked superiority in favour of either hand. I inclose also a specimen of bimanual drawing the left hand drawing the left face whilst the right draws the right face. The bimanual signatures attached afford strong evidence that I am naturally left-handed, for the right-hand writing represents a lifetime of practice, the left hand writing that of a few months only A most important matter is the fact that the right arm swings with the left leg and the left arm with the right. Is this the explanation of our ability to write backwards mirror fashion with the left hand more easily than in the opposite direction as in ordinary writing for in walking the hands move in opposite directions—i.e , there is a tendency to automatisation of movements in an opposite direction. If a person can be left-handed and left-footed and these conditions are dependent upon the superiority of the right hemisphere we ought to find a similar superiority of the left eye and ear I do not know whether other left handed people do the same or not but I have always noticed that though my hearing in both ears is perfect, yet I analyse sounds best on turning my left ear towards the source of sound. As regards the eye, though my sight is $\frac{6}{6}$ easily and my refraction E, I always retinoscopise with my left eye and for accurate as opposed to quick shooting prefer firing from the left shoulder indeed, I never fire from the right in target shooting It is common knowledge that though the vision is perfect in each eye and the refraction normal nearly every person has a "master eye", this is determined by holding a ring at arm s length with both eyes open and covering an object a few yards away A left-eyed person on shutting his left eye will find the ring too far to his left. If on the other hand he shuts his right eye he finds he is dead on" his object. This test shows that I am left-eyed. As regards experimental shooting my observations are founded on about 30 exceptionally intelligent subjects mostly professional men, each of whom fired 20 shots from each shoulder, the right eye sighting with right-shoulder shooting and the left eye with left shoulder shooting the shots being fired from the right and left shoulder alternately Left eyed men, and especially if left-handed, very frequently shoot 20 per cent. better with the left eye from the left shoulder One thing is beyond all doubt there was never what left-handed men who had always shot from the right shoulder expected—a very bad record for the left shoulder. Another point to which reference may be made is the almost invariably superior coördination of the right hand with the right eye. To show this facing $\frac{6}{24}$ of Snellen's type point promptly at the middle letter with the index finger of the right hand and shut the left eye. If right-handed the pointing is accurate. Now by pointing with the left index finger in the same way it will be found the pointing is accurate if the experimenter is left-handed, but inaccurate if he is right handed.



These remarks have been made without any knowledge of the literature of the subject, but I trust that they may prove of interest —I am, Sirs, yours faithfully,

CHAS WRAY F R C S Eng,
Surgeon Western Ophthalmic Hospital Ophthalmic Surgeon Croydon Hospital and Infirmary
Jan. 23rd 1903.

To the Editors of THE LANCET

SIRS,—The hand loom weaver mentioned by me in my communication in THE LANCET of Jan 17th, p 200 was not only ambidextrous but used both feet as well in working his machine His hands drove the pirn or bobbin, carrying the thread backwards and forwards in a groove or shuttle by means of an upright rod to form the weft of the cloth. This might be called pure automatism, but, at the same time, he could with either hand by a certain movement of a cord throw out of gear or start the mechanism when a thread broke or anything else went wrong The two hands were undoubtedly used for a common purpose but in a different direction, while either hand, left or right, could rectify any fault. In short, the left hand was as good and deft and necessary as the right, and each seemed as competent as the other In shoeing a horse the blacksmith pares out the feet with his left as deftly as with his right hand. Trimming the nails with knife or scissors, the mariner at his wheel, and the juggler tossing his brass balls in the ring are instances in point, not to mention the accoucheur whose left hand both in turning and applying the forceps has often to take on the duties of the right. The surgeon cutting down upon and tying an artery must be ambidextrous if anything His right hand must know what his left hand doeth , and the latter takes as important a position in the operation as the other

Sir William Gowers, in THE LANCET of Dec. 20th, 1902, p. 1719 in an interesting note on this subject says Every child seems to be born either handed , one handedness comes with development, partly from inherited partly from educational influences, &c. This places the whole scope and force of the discussion, as it were, in a nutshell. The child will as a rule, use the right hand first and become right handed and any tendency to left-handedness shou d be, and can be, great advantages of such temporary treatment and to the evils resulting from its abuse but also to the grievous losses entailed by certification in some cases of mental disorder of brief duration. This last argument I am assured weighed heavily with the Lord Chancellor but has been lost sight of in the present discussion

Sir William Gowers dwelt so exclusively on the advantages of single care that he has provoked Dr White and Dr Wood to write the papers recently printed in THE LANCET, principally demonstrating the evils that arise from it under the existing system

This discussion, in fact, emphasises what I have said else where—viz, that this mode of treatment demands the highest skill and experience, that it may be the best or the worst means of treatment and may mean salvation or perdition to the patient, and consequently that it is an abomination to allow it to be undertaken by any person however unfitted under any conditions however unsuited

My reason for writing to you arises from the fear that this revived discussion may suggest to the Lord Chancellor to defer the proposed clause until regulations have been framed to prevent possible abuses In this way almost indefinite delay may occur and it is this delay that I should wish to prevent. I would suggest, therefore, in order to avoid this result that there should be an addition made to the clause, requiring the Commissioners in Lunacy to report to the Lord Chancellor from time to time on the working of the clause and providing for the issue by that legal authority of regulations which should be directed to the restriction of the treatment of unconfirmed mental disorder to persons who had in some way satisfied the Commissioners of their fitness for this important and responsible work.

The existing state of the law tends to throw such cases into the hands of those who have little to lose by a prosecution, while persons of character and standing are deterred from taking them. The passing of the proposed clause would at once reverse all this. The fact of notification to the Commissioners and possible inquiry by them would encourage persons who had real qualifications for the work and would deter those who were unfitted. In this way the task of the Commissioners would be greatly simplified and a short experience should enable the necessary regulations to be framed. I am, Sirs, yours faithfully,

Queen Anne-street W Feb 28th, 1903 H. RAYNER

THE LONDON HOSPITAL

To the Editors of THE LANCET

SIRS,—I have just visited the London Hospital and I am convinced that there is a real danger of its work being cramped in every direction unless the public will respond really generously to the earnest appeal lately issued by its chairman and favourably received by the whole press.

It would be little short of a disaster if the largest hospital in England, situated as it is amongst the poorest people, could not properly carry on its beneficent work. More than that, I feel strongly that such work as is done at this hospital ought never to stand still but should progress, not only for the benefit of the sick and needy who throng its gates, but for the benefit of the whole country

The financial position of the hospital is sufficiently serious to justify me in taking the unusual step of giving a Mansion House dinner—which is fixed for May 4th—to make it more widely realised and to get for the hospital all the help I can

With a necessary expenditure of between £80,000 and £90,000 a year the income from the hospital's estate and investments is but £22 000, and even this must be seriously diminished unless £170,000 can be raised this year to meet the cost of essential improvements. The public may well be asked, I think, to help liberally those who devote so much time to working for the institution

Their Majesties the King and Queen are showing their interest in the London Hospital by having announced their intention after Easter to open the new out-patient department, which has cost £70 000 In this building are contained the new rooms for the cure of lupus by the Finsen light introduced into the hospital by the Queen herself

It would, indeed, be a gratifying result if their Majesties could be told on that occasion that the public had shown their appreciation of this gracious act by largely helping the hospital. With that view I shall be very glad to receive before then the names of those who are willing to help To commemorate this interesting visit the Lady Mayoress and I are proposing to endow a bed at a cost of £1000

I much hope that I may ask my fellow citizens and the public at large to assist in putting this great hospital into a sounder financial position and I invite your aid in bringing the matter prominently to the attention of the benevolent community

Contributions may be sent to me at the Mansion House.

I am, Sirs, your obedient servant,
MARCUS SAMUEL, Lord Mayor

The Mansion House, E C, Feb 28th, 1903

THE LARGE INTESTINE AS AN INTERMITTENT SYPHON

To the Editors of THE LANCET

SIRS,—I was glad to see in THE LANCET of Feb. 21st, p 552, a letter from Dr R. W Leftwich on the above subject which from its great physiological interest and multiform clinical bearings deserves in a high degree the notice of the profession In his original paper, published in the *Edinburgh Medical Journal* of December, 1902, the author adduced, as it seemed to many of us, several strong reasons, both theoretical and experimental, for accepting the truth of his thesis that the action of the large intestine is syphonic, not peristaltic. Although he contended that the continuous tonic contraction of the longitudinal muscular bands which he believed to exist was not essential to the truth of his doctrine he emphasised its importance, while recognising that it was largely hypothetical. In his letter to THE LANCET he now quotes a statement by Dr T G Brodie to the effect that there can be no question that the longitudinal bands of the colon are tonically contracted It seems to me that if such be the case Dr Leftwich has triumphantly proved his hypothesis and is to be credited with a striking and valuable addition to knowledge arrived at by a strictly scientific method. He has, I think, established the entirely original point that the large intestine, being, broadly speaking, a bent tube with a short ascending and a long descending limb, fairly rigid walls, and contents capable of flowing, must, of physical necessity, act as a syphon.

From a purely physiological point of view this new light thrown on the functioning of an important organ of the body is of remarkable interest But, as Dr Leftwich shows in his paper in the *Edinburgh Medical Journal*, this new explanation of the action of the large intestine has also a very practical and varied bearing on clinical medicine. Not only does the theory of syphonage interpret to us the meaning of many incidents connected with orderly and periodical defecation, but it also may help us in the scientific treatment of various disorders of intestinal action. Whether or no "appendicitis" be more frequent now than in the quite recent times when it was multi titular, the suggestions of Dr Leftwich as to its causes and treatment are not to be disregarded, and I am inclined to think that this new view of the working of the large intestine may have considerable influence in regulating or checking some forms of active treatment of intestinal and other disorders Much good may come of the practitioner's daily opportunity of quiet reflection on the function of his own internal syphon.

Although Dr Leftwich, in his letter to you, has only asked for help in the explanation of certain side issues in connexion with his theory, I have ventured to comment here on the new doctrine alone which he has so ably propounded, being of opinion that the importance and originality thereof have been hitherto but imperfectly recognised His short paper of a few pages gives more to think about than some large treatises

I am, Sirs, yours faithfully,

London W Feb 26th 1903 H B DONKIN

THE IMPERIAL YEOMANRY HOSPITALS

To the Editors of THE LANCET

SIRS,—In your review of the record of "The Imperial Yeomanry Hospitals, South Africa," in THE LANCET of Feb 14th, p 445 an error has somehow crept into the reference presumably, to the Imperial Yeomanry Hospital, Pretoria. This hospital was a *yeomanry* general hospital of some 600 beds sent out from England by the Imperial Yeomanry Hospital Committee and was situated about two

2689 per 10,000, on the other hand, no less than 7563 were passed in 1899 and 5439 in 1897 at the low measurement of 32 to 33 inches. From these details we may judge how far the average recruit conforms to those physical qualities considered necessary for weight-carrying under chest constriction, for prolonged exertion, for long marching, and for sudden calls upon the vital powers, and what relation he bears to the average of his race, assuming that a height of 5 feet 7½ inches, a weight of 150 pounds, and a chest girth of 36 inches may be taken as an index for males between 18 and 19 years of age Surely in the youthfulness and immaturity of body of the individuals subjected to army duties and requirements we have an explanation of no small part of the wastage in the early years of service quite outside that dependent on the deleterious agencies of the municipal conditions under which they have been born and brought up. From a consideration of the views of army surgeons at home and abroad the late Professor E. A. Parkes placed the lowest desirable recruitage at 20 or 21 years and from a consideration of the physiological growth of the body, and especially its osseous and muscular tissues, wrote, "These facts show how wrong it is to expect any great and long continued exercise of energy from men so young as 18 and 20, and what will be the inevitable consequences of taxing them beyond their strength" Two recent anonymous writers, one in the *Times* of Feb 4th and the other in the *Fortnightly Review* of the same month, speak the one of "the miserable weeds that form the bulk of the recruits for the British Army," and the other (in India) of "the weedy undersized recruits who figure so prominently in our ranks,' and the foregoing physical details corroborate these opinions. But as regards the subject started by Sir F Maurice recently, what we want first to ascertain is the proportion of the breakdowns from youth and immaturity of body in the three out of five wastage (and we may add also that for desertion) in order satisfactorily to settle what remains as a groundwork from which to gauge the health status of our race Be the health standard the highest attainable the age factor in the army problem will still remain.

And, secondly, in respect to the bearings of the army data on the assumed decadence of our community we have for guidance the causes of rejection in the recruiting room and the invaliding and mortality of early military life The latter information is not available but the former are as follows, taking the more important ones and giving them in the tabular form as set forth in the Army Medical Report of 1898, for example —

—	Ratio per 1000 rejected	Ratio within three months of service
Under chest measurement ..	73 88	0·05
Defective vision ...	42·64	0·09
Under weight ...	34 82	0·02
Loss or decay of many teeth	26 34	0·22
Under height	21·79	0·03
Disease of heart	17·26	0·60
Defects of lower extremity (fracture contraction, luxation	17·72	0 35
Disease of veins	15·74	0·21
Impaired constitution and debility	5 49	0·45

To these we may append the frequent official remark that the 'largest number of rejections was caused by defective development (under height, weight, and chest measurements)" and to make the rejection ratio within three months of service more complete we must add that higher than any of those enumerated stand diseases of the nervous system and weakness of intellect, the former amounting in 1897 to 0 85 per 1000 and the latter to 1 27 Now, if we are right in assuming that defective vision and loss of teeth from decay are, in part at least, to be classed also under developmental deficiencies or defects we come to this conclusion that the main causes of rejection indicate conditions bearing on the limited sections of the community from which the army draws its numbers inimical to normal development and evolution of the body, and we have to go some distance down the list of rejections before we arrive at what are properly disease states, among which figure prominently lesions of the vascular system, these lesions figuring also in the invaliding lists of early military life. And herein seems to me to reside the true bearing of army data on the national health question. The figures show beyond doubt that operating on the sections which are led to take up military life less as a voluntary matter (for to such a procedure the term "voluntary" is as much a misnomer as when applied to the process of taking food and drink into our bodies) than under the stress of economic causes, there are agencies antagonistic to normal development, producing stunted frames incapable of meeting such physical demands as military service produces and in a less degree engendering actual disease states, but in themselves they do not warrant the deduction that the recruit defects characterise the community generally From a consideration of this subject from the national side and from the army side two duties of the community stand out clearly the one of rectifying the defects of town existence by providing wholesome housing and conditions offering the chance of an attainment of a good physical and moral standard to our poorer brethren, the other of undoing the moral wrong which now rests upon us of subjecting immature lads to army conditions which by clear experience we know no small number of them to be incapable of meeting and which, while adding in no way to military efficiency or strength, do add to the physical deteriorations brought about by the prior unwholesome circumstances of town life.

I am, Sirs, yours faithfully,
FRANCIS H WELCH,
Surgeon Colonel (retired) Army Medical Service
Brandram road Lee, S.E, Feb 21st 1903.

MALARIA AND MOSQUITOES

To the Editors of THE LANCET

SIRS —In the correspondence that has been going on in the columns of the *Spectator* under the heading "English Winds" great stress has been laid by some of the writers on the fact that although ague has disappeared from certain parts of England, notably East Anglia, for a good many years, yet in the neighbouring parts of Suffolk anopheles are far from being extinct and that in the "Broad district" they are still to be found in large numbers. A statement like this so authoritatively made should be met by investigation at the hands of the supporters of the mosquito theory of malarial fevers to clear the doubt, as the place is much nearer than Sierra Leone.

I am, Sirs, yours faithfully,
P J DAMANIA
Lieutenant-Colonel late I.M.S
Whitehall-court, S W Feb 28th 1903.

⁎⁎⁎ The anopheles cannot convey the malarial poison unless it is able to feed on the blood of men or animals already suffering from malaria.—ED L

ASEPTIC AND ANTISEPTIC SURGERY

To the Editors of THE LANCET

SIRS,—It is very helpful to young surgeons to hear from such an authority as Dr James Laurie that all that is needed to carry out successfully the aseptic method *in private practice* is "a kettle of boiled and one of boiling water and plenty of freshly laundried towels." It would be interesting to me to know whether Dr Laurie uses the kettle as a steriliser and, if so, it must of necessity be a fish kettle in order to hold the necessary instruments, as the common tea kettle is not very well suited to the purpose Let us suppose the operation to be an amputation in a cottage far removed from enlightened aseptic surgeons either on this side of the border" or on the other Our steriliser is singing on the hob, there is no fish kettle, and the saucepans are at present full of porridge (and would take some hours to render aseptic), and our saws and scalpels will not go in Where do we look next for a suitable steriliser? If the surgeon has not brought his own fish kettle and freshly laundried towels he is aseptically up a tree. Being an aseptic idealist he may have a steriliser with him, of course, he is then absolutely safe and may begin work But—and it is a very big but—a steriliser means at best an extremely bulky addition to his surgical bag, which in his private practice may have to be carried many miles to the place of operation, and then, again, the ideal aseptic surgeon corrected There are still many unappropriated facts, as Mr Wallace would say, which might be brought forward in evidence to prove that right handedness is due to a great extent to influences outside the body, though inheritance and bodily idiosyncrasy cannot be overlooked. Apologising for taking up so much space in your columns on a subject though of great interest of not much practical importance,

I am, Sirs, yours faithfully,
JAMES MORE, M D Edin
Rothwell Northamptonshire, Feb 28th 1903

APPENDICITIS

To the Editors of THE LANCET

SIRS,—Without reference to Professor Bourget's plan of treatment no discussion on this very important question can be considered complete. Bourget does not hesitate to use leeches if indicated or to purge his patients with castor oil if needful, but he places his chief reliance on warm anti septic injections passed through a long tube so as to get beyond the sigmoid flexure and so wash out the hepatic flexure and even the cæcum itself Bourget declares that when this is done pain and tension cease as if by magic that the temperature falls and agony is at once replaced by repose, sleep and speedy restoration to health. He points out that even if pus be formed it may be absorbed or discharged innocuously into the bowel or come to a head on the surface, also that removal of the appendix is no guarantee against subsequent attacks and that it is only when the parts have become gangrenous or are approaching that condition that operation is indicated or is really necessary Bourget has treated a number of cases during the last ten years, he gives minute details of 26 cases and declares that he has had no operations, no accidents, and not a single death—"aucun cas de mort.[1]" Such was my experience when a student in the wards of the Royal Infirmary of Edinburgh and subsequently in the rare opportunities I have since had of seeing cases of typhlitis, perityphlitis, or appendicitis Certainly in former times such cases were rare, those afflicted did not die and as a rule were no worse off for what they had undergone. According to Chauvel's statistics of the French army the old fashioned treatment compares favourably with the present system of almost constant excision, and I must say that I cannot bring myself to believe that any portion of the human body exists only for the production of disease or removal by operation or that things have so violently changed that a disease which was rare and easily dealt with and almost never fatal 20 years ago should without obvious cause become exceedingly common, very fatal, and require operation in 80 out of a 100 cases Of course, where the peritoneum is bathed in pus and the parts are gangrenous or approaching that condition operation is imperative and we ought to be thankful indeed that we have among us so many profound clinicians and excellent surgeons who open the abdomen with so much skill and such splendid results.

I am Sirs, yours faithfully,
Nottingham Feb 28th 1903. C BELL TAYLOR, M D Edin

THE NATIONAL HEALTH AND ARMY RECRUITING STATISTICS

To the Editors of THE LANCET

SIRS,—In sequence to my letter in THE LANCET of Feb. 7th, p 397, on the above topics I would ask you to allow me a little more space further to elucidate the bearings of the army recruiting statistics on the asserted wastage of military strength, expressed as a loss of three out of five between application at the recruiting office and the end of the second year of service, and the grounds which they offer for an impeachment of the national health I base my remarks on the information given in the Army Medical Reports for the years 1897–1900, not taking these four years as specially applicable to the matter in hand but merely as being the latest and most convenient for the purpose, the period embraced being sufficient for a fair deduction—as indeed any similar period is within the last 30 years, the recruiting ground throughout remaining the same and the yearly divergencies in the major details being but fluctuations brought about by changes in the standard adopted in accord with the army needs of the time. From the figures and details to be adduced I think that the readers of THE LANCET will be in a position to form a conclusion on the question raised so far as the army data can assist thereto And first as to the recruit supply During these four years there was a total of 278 977 applicants for army employ and of these 188,061 were accepted and 90,916 were referred to civil life, the yearly average of inspected being 69 744 and the yearly ratio of rejected being 329 10 per 1000, though if the further rejections within three months of service be added this ratio is increased to 336 44 Such a large elimination of one out of every three points clearly either to a high standard of necessary qualifications or poorness of the human material available for army purposes under the conditions which exist That the latter is the true reading there is no doubt, most probably, concurring with the anonymous writer of "The Problem of the Army" in the *Times* of Feb 4th that the standard is "appallingly low" Of the divisions of the United Kingdom furnishing the applicants in each 1000 England and Wales give 762, Scotland 96, Ireland 129, and the colonies and stations abroad 13, though if we compare the numbers with the total male population of each section according to the last census we find that while each contributes a fair quotum to the sum total Ireland is somewhat in advance of the other two and Scotland gives the lowest rates, it requires, however, to be borne in mind that locality does not connote nationality and that the recruits from England and Scotland contain a fair proportion of men of Irish descent. Tested by the ratio of rejected to inspected the colonies and stations abroad give the best results, then follows Ireland, while Scotland and England and Wales closely approximate in the maximum ratio

The classifications of the previous occupations of those seeking army employ are as under, the number for the year 1898 being taken as a fair index for the whole period except in the boy class which varies considerably in years —

—	Proportion per 1000 inspected.	Ratio of rejection per 1000.
Labourers, servants husbandmen	657	351 41
Manufacturing artisans (clothmakers weavers lace-makers) ..	139	395·05
Mechanics (favourable to physical development)	92	334 36
Shopmen and clerks	72	370·09
Professional occupations students &c.	9	320·40
Boys under 17 years of age	31	169·37

These figures indicate how limited as to social strata the army mass is and how vastly the sons of manual toil predominate, they show also the better physical status of the boys. As might be anticipated the indoor workers head the rejection ratio, while the too high ratio of the outdoor workers shows the existence among them of causes antagonistic to physical well being

Passing now from those inspected to those received into the service we have figures dealing with the age and physical qualities. The ages are arranged in years, mainly between 17 and 25, and the most numerous group in the whole period is between 18 and 19—about 4400 in every 10 000. That between 19 and 20 comes next with about half this number and these two groups constitute three-fifths of the whole mass, on the other hand, the 17 to 18 group varies considerably in some years and the group 24 to 25 is a very small one—about one-fortieth of the whole It is apparent that youthfulness is a marked characteristic of those entering the military service and this potent factor must correspondingly influence the results. In respect to height the most numerous group is 5 feet 5 inches to 5 feet 6 inches, corresponding to 18 to 19 age group, and next 5 feet 6 inches to 5 feet 7 inches group, on the other hand, group 5 feet 8 inches to 5 feet 9 inches gives a considerable decline and group 5 feet 4 inches to 5 feet 5 inches marked fluctuations, in 1900 giving a ratio almost as high as the maximum group In respect to weight, those between 120 and 130 pounds are most numerous, then follows those between 110 and 120 pounds and at a lower ratio those between 130 and 140 pounds. In respect to chest girth, from 33 to 34 inches constitute the largest group—about 3019 in each 10,000, 34 to 35 inches group gives about of its management, but it is undoubtedly contrary to the laws of the hospital applying to the medical staff and in that sense illegal Law 40 provides "that no medical officer shall be removeable except by the vote of a general or special court on the report of the committee of management", but the committee made no report that I have heard of or seen, hence a serious step has been taken against me and I have suffered injury unheard and without sufficient or any cause being assigned. As this is a matter which affects the position of the medical and surgical staffs of all hospitals it is one which, I venture to think, will attract the attention of medical journals and through them of the profession at large I am, Sirs, yours faithfully,

---

Grosvenor-street, W March 2nd, 1903. H. A. REEVES.

[COPY OF LETTER FROM SECRETARY]

ROYAL ORTHOPÆDIC HOSPITAL, Feb 27th 1903

DEAR SIR,—I have to inform you that at the annual court of governors held yesterday you were not re-elected upon the committee of management from which you some time ago gave notice of your intention to retire.

The governors did not re-elect you either as one of the honorary surgeons, but thinking you would prefer to finish the treatment of certain of your patients no immediate steps have been taken regarding the appointment of a successor

I am, dear Sir yours faithfully

H. A. Reeves, Esqre. TATE S MANSFORD

THE VALUE OF CHLORETONE IN SEA-SICKNESS

To the Editors of THE LANCET

SIRS,—I can confirm the good opinion expressed by Dr L. Wheeler in THE LANCET of Feb 28th, p. 615, as to the value of chloretone in sea sickness. Last June, when about to cross the North Sea, I was, by the courtesy of Messrs. Parke, Davis, and Co, furnished with a supply of the drug in five-grain capsules. I may say that I am a very bad sailor and that, rough or smooth, a sea voyage has for many years meant at least 48 hours of abject misery, the North Sea having especial terrors. On this occasion before leaving the Humber I took one capsule and on retiring to my berth I took two capsules more. During the night and all next day it blew hard, with a nasty cross sea, yet I was perfectly comfortable and did not miss a meal Early in the morning of the first day at sea I met the stewardess, she was looking very ill, and she told me that all the lady passengers were sea sick and that she herself was in the same plight and was hardly able to attend to her duties I administered two capsules to her at once and put my stock at her disposal for the ladies On inquiring the result the stewardess told me that she got speedy relief and could take food and go about her work comfortably and that every lady who had taken a dose said that she felt very much better On the return journey sailing from Christiania, we had a lovely run down the fiord and I went to bed while the ship lay by the quay side at Christiansand and quite forgot both sea sickness and my remedy The night was a very rough one and next morning no breakfast could be served in the saloon, the few who could eat being supplied in their cabins. I was very bad and could take neither food nor stimulant. Somehow I managed to dress—or rather put on my clothes—and make my way to a saloon where, lying on my back athwart ship, I slid backwards and forwards for an hour or two. Then I bethought me of chloretone and sending a steward for my bottle I took two capsules. For an hour afterwards I rested comfortably and at luncheon time took my place at table and ate a good meal. I am, Sirs, yours faithfully,

J W FAWCITT, L.R C P & S Edin

Broughton-in Furness, March 2nd, 1903.

THE "FRICTION" TONGUE

To the Editors of THE LANCET

SIRS,—The above term may very fitly be applied, I think, to an appearance of the tongue which is very commonly seen in people who have worn an upper teeth plate for some time. In extreme cases the whole upper surface shows a smooth dry, polished, and bright red surface, the raphe becoming shallow and indistinct and in some cases entirely obliterated.

Dr W A. Wills in writing of chronic glossitis in Allbutt's "System of Medicine" says that "if general it is often called glossy tongue and is usually the result of chronic dyspepsia or alcoholism." In the "friction" tongue—a true glossy tongue—we have neither of the two above causes at work. People who use an upper teeth plate may be the subjects of dyspepsia or alcoholism and in them the friction effect may be seen in its most typical form. But neither chronic dyspepsia nor alcoholism, or both combined, produce such a well marked condition of glossy tongue as that found from the use of an upper teeth-plate. There is no pain or tenderness or any inconvenience accompanying this appearance of the tongue, indeed, the possessors of such never make any complaint of it or know that there is anything unusual in the appearance of it. In itself, therefore, it is a matter of no importance and its only claim to be recorded is simply to have attached to it its proper causation and nothing more. It is thus that I have termed it a friction tongue—a mechanical result.

I am Sirs, yours faithfully,

Boyson road S.E. March 2nd WM ECKLIN, M B Glasg

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

A Crematorium for Calcutta.—The Census of Calcutta —The Plague Epidemic —A Magnificent Donation to India.

THE movement which was started at the end of last year with the object of establishing a crematorium for Calcutta has rapidly progressed The Cremation Society of Bengal is to be enrolled as a company and has succeeded in getting the corporation of the city to purchase two bighas of land (about two-thirds of an acre) adjoining the large Christian cemetery and to allot in the coming year's Budget Rs. 15,000 (£1000) for the erection of a crematorium. This, I understand, is everything that was asked for and it now merely remains for the society to obtain funds in order to build a chapel. In a year's time the crematorium should be built and in working order

The Resolution of the Government on the census of Calcutta has just been issued This city, with its suburbs, has a population of 949,144, and if Howrah, on the opposite side of the river (the position of which corresponds with that of Southwark in London), were included the combined aggregation of people numbers nearly 1,107,000 The municipality of Calcutta, however, controls an area having but 847,796 persons, as the suburbs have their own little governing bodies. The population has increased during the past decade 24 per cent.—chiefly by immigration, especially from Behar and the United Provinces. One curious feature exists in the large predominance of males—the proportion of the sexes being as 19 to 10 Of the total, 65 per cent. are Hindus, about 30 per cent. are Mahomedans, and about 4 per cent. are Christians, the small remainder being constituted of members of various nationalities. There are no less than 59 languages spoken in Calcutta, of which the chief two are Bengali and Hindustani, Uriya and English following a long distance after It will hardly surprise anyone to learn that three-fourths of the population are illiterate.

The mortality from plague throughout India mounts up higher and higher There were no less than 24,500 deaths from this disease alone during the past week. These figures compare with 23,632 deaths during the previous seven days and 12,192 during the corresponding week of last year The details published are Bombay Presidency, 11,708 deaths, the Punjab, 2882, Bengal Presidency, 2757, the United Provinces, 2510, the Madras Presidency, 793, the Central Provinces, 1173, the Mysore State, 829, Hyderabad State, 622, Berar, 595, Calcutta, 97, Bombay City, 498, and Karachi, 20 Poona is not mentioned, but the daily records show over 100 deaths a day from plague alone, which with a population of only about 100,000 indicates the frightful ravages which the disease is making once more in that city

Mr Henty Phipps has placed at the disposal of the Viceroy the munificent donation of £20,000 to be devoted by the Government of India to some object of practical benefit by scientific or industrial research which will promise enduring good to India Mr Phipps is a partner of Mr Andrew Carnegie. He has also given £2000 to the Victoria Memorial Scholarship Fund which has for its chief object the training of native women as midwives and nurses. This fund has already reached something like six and a half lakhs of rupees and is presided over by Lady Curzon.

Feb. 5th.

will, of course, have his aseptic gauze in metal sterilisers—perhaps two or more

How can anyone state that it is as sure of success, and therefore as suitable to the conditions of private practice, to attempt to carry out an operation aseptically as with the aid of antiseptics when the operator must cart an array of tin boxes and an unwieldy steriliser to his patient's house when he is more certain of getting a good result by taking a bottle of pure carbolic or a few soloids, let us say, in his waistcoat pocket? The surgeon in private practice may have to obtain the assistance of a nurse who has had little or no training, does Dr Laurie mean to say that he would hope for a better result with no antiseptics than with them if he and his anæsthetist were the only medical men attending at the operation? I am speaking of the thousands of cases where the theatre is a small bedroom, the nurse a district nurse or even a trained surgical nurse, the patient most likely a working man with a strangulated hernia, and the only way of procuring instruments, anæsthetic, dressings, and all the various items required being to bring them yourself, knowing that it is better to take a little "trouble" over preparations even if you do happen to be a believer in antiseptics than to risk leaving everything to an assistant who apologises and remarks that he has forgotten the needles when you are ready to sew up the wound. It is simply delightful to hear Dr Laurie twitting Mr Watson Cheyne on his antiseptic theatres. One would think that men from all points of the civilised world flocked to Glasgow to see Surgery, with a capital S, stopping on their way to have a look round London and get lunch before going on in fevered haste to the home of aseptic surgery I wonder why Lord Lister could not see that he was ruining his career by coming to "Mr Watson Cheyne's side of the border"

By the way, I can call witnesses to prove my statements when I say that on one occasion I watched a beautiful ideal aseptic operation performed in what is perhaps the most aseptic theatre in the kingdom The operator wore rubber boots and rubber gloves, but, alas, the nurse dragged the ribbon of sterile gauze along the beautiful tiled floor and the surgeon stuffed it into the wound and turned round to talk to the crowd of distinguished foreigners on the ideal method of surgical procedure There were no antiseptics there, the tape had been sterile and it would remain in the wound with the dust off the floor undisturbed by any antiseptic which *might* counteract the effects of the carelessness displayed in a theatre given up to aseptic surgery Would a patient have a better chance in a little country cottage with a "kettle of boiled and one of boiling water and plenty of freshly laundried towels"? I might say that I have operated without the above-mentioned kettles many times and, thanks to antiseptics, despite the absence of aseptic theatres, nurses, and other ideal surgical luxuries, have had good results. Perhaps Dr Laurie may say I am no judge of good results because I acted as house surgeon to Mr Rose and Mr Carless who used, and still use, antiseptics and, I believe, still have cases that recover, and even do well, under their old world treatment.

In conclusion, I should like to say that I am not bigoted. I have acted as house surgeon to aseptic surgeons as well as antiseptic surgeons and have found that with the usual amount of "trouble" one can get and can expect better results *with antiseptics* in private practice I do not mean the practices of a few dozen men in our great cities but the practices of hundreds of thousands of men scattered over both sides of "the border" Asepsis may be the ideal method, but surely everyone who has tried both methods must find that ideals are difficult to obtain in the general run of private practices and therefore the practical, convenient, and far less expensive well tried "antiseptic method" will hold its own except under such conditions as may be obtained in aseptic theatres, preferably of course, not on "Mr Watson Cheyne's side of the border"

I am, Sirs yours faithfully,
IAIN JEFFERISS, M.R.C S Eng, L.R.C P Lond.

London Feb 28th 1903

"RELAPSES" IN SCARLET FEVER

To the Editors of THE LANCET

SIRS,—If Dr A B Sloan's article in THE LANCET of Feb 14th, p 436, should require corroboration I give two cases which occurred in the Biggleswade Isolation Hospital

A girl, aged three years, was admitted on Nov 5th, 1902, with a scarlatinal rash and a temperature of 101° F She peeled as usual On Nov 29th she came out in a universal scarlatinal rash and again desquamated freely

A girl, aged 13¼ years, was admitted on Dec. 16th, 1902, with a scarlatinal rash and a temperature of 100 4° F She desquamated in due course. On Jan. 24th, 1903, she came out freely in a scarlatinal rash and again peeled freely

These two cases occurred out of 60 scarlatinal admissions during 1902–03. I am Sirs, yours faithfully,

Biggleswade, Feb 17th 1902. J B EMMERSON.

THE DISPOSAL OF THE SEWAGE OF LONDON AND THE CONTAMINATION OF SHELL-FISH

To the Editors of THE LANCET

SIRS,—It is interesting to one who, from the first, condemned the method of disposal of the sewage of London (which was adopted by the Metropolitan Board of Works in defiance of the recommendations of the Royal Commission on Metropolitan Sewage Discharge and has been continued since) to find that the Conservators of the rivers Thames and Medway and also a joint committee of the Port Sanitary and Sanitary Committee of the City Corporation have adopted a resolution, stated in the *Times* of Feb 26th —

> That the present system of discharging sewage into the Thames estuary is dangerous to health and detrimental to an important food-supply and that representations be made to the *Local Government* Board with a view tolegislation being initiated to effectually deal with the matter

In my presidential address to the Society of Medical Officers of Health in October, 1888, after stating the recommendations of the Royal Commission and pointing out that the Metropolitan Board of Works and its advisers were flouting them, I concluded as follows —"I protest in the name of the Society of Medical Officers of Health of this country against such a state of things and against the further carrying out of a scheme which, while being enormously costly, will not only not settle the question, but will rather increase the difficulties of settling it effectually and will be pointed out by succeeding generations as a disgrace to the sanitary work of the nineteenth century" And in the *discussion on papers* by Mr Worth and Mr Santo Crimp on the Main Drainage of London and by Mr Dibdin on the Purification of the Thames before the Institution of Civil Engineers in February, 1897, I stated that ' I could not help thinking that if the money which had been spent in trying to purify the sewage of London by means of precipitation and filtration had been spent in taking it out further, as had been proposed, to the Maplin Sands or some other suitable place, and disposing of it by irrigation, that money would have been very much better spent, and I thought that would be resorted to in the end, however much money might be spent on experiments."

On that occasion Dr Dupré, one of the former chemical advisers of the Metropolitan Board of Works, "expressed sympathy with Professor Corfield, who had predicted that the river would be more foul after the scheme had been in operation than before' This statement was not strictly correct, but that may pass, and it is now my turn to sympathise sincerely with Dr Dupré on the condemnation of the scheme he defended by the most important sanitary authorities connected with the river Thames

I am, Sirs, yours faithfully,
W H. CORFIELD, M.A. M D Oxon. F R.C P Lond.,
Consulting Sanitary Adviser to His Majesty's
Office of Works

Savile-row W March 2nd 1903

ROYAL ORTHOPÆDIC HOSPITAL

To the Editors of THE LANCET

SIRS,—I inclose a copy of a letter which the secretary of the Royal Orthopædic Hospital was directed to address to me and which sets forth that at the recent annual meeting of the governors I was not re-elected. I was not present at this meeting, nor were any of the governors who were opposed to the sale of the site, several of them having resigned disapproving of that policy I am not aware that any reason was given for my non election, nor have I received any complaint about my work. It remains to be seen if this unprecedented action will be in the interest of the hospital or to the credit increased degree to suggestions made in various parts of the country that hospitals should be placed entirely under the care of the municipality, so that the burden of their support should fall equally upon all classes of the community able to help The Lord Mayor expressed his private opinion that hospital patients who could afford to pay for their own food ought to do so and in regard to those who could not afford payment for that purpose it would be reasonable that the Poor-law authorities should pay for their food. He made that suggestion to the committee of the hospitals. I fear that his lordship's suggestion will meet with scant favour from the public, as if it were adopted the better class of hospital patients would be placed on the same footing as the inmates of a workhouse hospital.

Small-pox in Liverpool Proposed Opening of Vaccination Stations The Overcrowding of Electric Cars Proposed Quarantine for Ships

105 fresh cases of small-pox were reported to the health authorities during the week ending Feb 26th, as against 54 during the preceding week. 77 patients are isolated for observation. There had been five deaths from the disease during the week. 310 patients were under treatment in the corporation infectious hospitals at the above date. Considerable discussion took place at the recent meeting of the Toxteth board of guardians as to the best means of coping with the alarming spread of the disease in the Toxteth Park township. A resolution was carried to the effect that application should be made to the Local Government Board to reopen the vaccination stations. In spite of the protests from many quarters, including that in THE LANCET of Jan. 10th, p 135, the electric cars are still disgracefully overcrowded and thereby have become a positive danger to public health. At the ensuing meeting of the city council Councillor Byrne has given notice that he will propose the following motion —

> That the Parliamentary Committee be instructed to apply for powers to enable the port sanitary authority to deal with ships arriving in the Mersey infected with small pox in the following manner To detain the ship in the river for a period not exceeding 48 hours during which time the ship and crew shall be thoroughly disinfected and the crew vaccinated before entering dock also that a special steam launch be provided fitted with all necessary appliances for dealing with such cases.

Liverpool Infirmary for Children Donations towards the Cost of a New Building

£22,000 have been already promised in aid of the erection and furnishing of a new infirmary and the out-patient department (recently opened), the total cost of which is estimated at £60,000

Liverpool Abattoirs Question

An influential deputation representing the Royal Infirmary, University College, and the medical profession of the city relative to the renewal of the leases of the abattoirs in Trowbridge-street, waited on the estate committee of the City Council recently Mr John Lawrence, the vice-chairman of the finance committee of the city council, in introducing the deputation stated that it was understood that the estate committee was contemplating the renewal of some leases in connexion with the Liverpool abattoirs and referred to various reports and resolutions of the council disapproving of the neighbourhood of Trowbridge-street as a site for abattoirs Sir William Banks quoted from reports by Dr Trench and Dr T Stopford Taylor, former medical officers of health of Liverpool, and also by Dr E W Hope, the present medical officer, tending to show that the existence of an abattoir, however well conducted, was injurious to the health of the neighbourhood, besides being offensive to the senses The chairman of the committee (Mr R A. Hampson) thanked the members of the deputation for their attendance and stated that the committee and the council were in sympathy with their views and were concerned as to the best way of dealing with the question The deputation could take it as settled that the corporation would never seek to continue the abattoirs in the centre of the city after the expiration of the leases The committee had recently successfully negotiated with the Abattoir Company to arrange the termination of the various leases affecting the Abattoir Company's premises at the end of 1911. The chairman assured the deputation that they had no intention of renewing any of the Abattoir Company's leases but that recently some lessees of the corporation had assigned a timber yard adjoining the Abattoir Company's premises to the company for lairage purposes. The corporation was unable to prevent this assignment being made, but had been able to arrange with the Abattoir Company that the assigned leases should terminate on the date fixed in respect of the remainder of the Abattoir Company's premises and that the premises should not be used for the purpose of slaughtering cattle. Mr. J Kewley, the chairman of the committee of the Royal Infirmary, Mr Robert Gladstone, Principal Dale of University College, Dr William Carter, and others also addressed the committee in opposition to the renewal of the leases.

The New Liverpool University

Mr. John Lawrence, the vice-chairman of the finance committee of the city council, announced at the last meeting of the committee that a letter had been received from the Clerk to the Privy Council stating the decision of the Privy Council to grant a charter to the new university conditionally

Work of the Police Force Ambulance and other Police Services during 1902

The annual report of the head constable of Liverpool states that there are now six fully equipped horse ambulances stationed as follows in the city Royal Infirmary, Royal Southern Hospital, David Lewis Northern Hospital, Stanley Hospital, Central Fire Station (for night service), and Old Swan Police Station (for outlying districts). The number of turns-out during the year was 2759 1729 constables and others hold certificates from the St. John Ambulance Association and 1288 constables hold medallions. The number of cases of first-aid rendered by the police was 699 Out of this number 498 were adjudged by medical men to be worthy of special commendation 66 lunatics were found wandering in the city and taken charge of by the police One sergeant received a silver medal and a vote of thanks from the Liverpool Shipwreck and Humane Society for saving life from poisonous fumes, whilst another constable was awarded the bronze medal by the same society for saving life from drowning

March 4th.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary

THE inhabitants of Cardiff and of the surrounding districts appear at last to have realised their responsibilities and to have determined that the Cardiff Infirmary shall no longer be starved for want of funds Since 1893 the yearly expenditure has always exceeded the income until in 1899 there was a deficiency on the year's working of over £2000 and an accumulated debt of £12,000. The mayor who came into office in 1900 inaugurated a fund for the purpose of liquidating this debt and his efforts were seconded by the proprietors of the *Western Mail*, who besides subscribing generously themselves initiated a shilling fund which was so well supported that within a few months the entire debt was cleared off. Although in each succeeding year the income has not been sufficient to meet the expenditure the financial report presented at the annual meeting of the governors held on Feb 25th showed an adverse balance for last year of only £155 notwithstanding that the expenditure amounted to £10,690, the largest sum which has been spent in any one year since the establishment of the infirmary The number of in patients treated during the year was 1878 Ten years ago the yearly expenditure was £6010 and there were 1339 in-patients treated. The most gratifying portion of the report for 1902 is the statement that the workpeople's contributions have increased by £1221 and have reached the creditable sum of £3540. In the ordinary subscriptions there was an increase of only £76. This substantial support by the workmen may in great part be due to the admission to the board of management of some of their number and these representatives have no doubt satisfied themselves that the adverse criticism to which the institution was subjected a few years ago was in no way warranted. In a supplementary report issued by the managers there are set out in some detail several building additions and improvements which are considered to be necessary for the efficient working of the hospital and the separate cost of these works as ascertained by public tender is appended. They amount altogether to £5329 and include fire hydrants to cost £450 laundry improvements £200 terrazzo flooring £236, and intercommunicating telephones £106. It is

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The University of Birmingham

THE annual meeting of the court of governors was held on Feb 18th In the absence of the Chancellor, the Right Hon. Joseph Chamberlain, M P , the chair was taken by the Vice-Chancellor, Alderman Beale. The report and balance sheet were taken as read, copies of the same having been distributed. The Vice-Chancellor then sketched the progress which had been made during the past year Four new chairs had been established, two in connexion with subjects which had not been dealt with before—namely, history and metallurgy—and two with subjects in connexion with the faculty of commerce which had been dealt with in a more or less perfunctory manner—viz., mining and accounting The council had resolved to establish a chair of education, but had not yet been able to arrange to fill it to their satisfaction The difficulty of carrying out the work of the University in the present buildings was dwelt upon and it was stated that the arrangements for the new buildings at Bournbrook were progressing satisfactorily Sir Oliver Lodge gave an address upon the requirements of teaching in relation to science and to the new school of modern languages and made some emphatic remarks upon the training of secondary teachers. He urged that training colleges should not be detached from places of learning in general. A memorial was presented by the students in favour of some rearrangement of the course so as to leave every Wednesday afternoon free. A similar memorial was presented last year and was referred to the Senate. The undergraduates are now willing to sacrifice Saturday mornings if they can succeed in obtaining Wednesday afternoons for athletics and recreation or for independent studies The curriculum of the medical students entails many difficulties in the way of the adoption of this suggestion. The matter has been referred again to the Senate which, it is hoped, may concede the request.

The Eyesight of the Poor

About a year ago the board of guardians appointed an ophthalmic surgeon to test periodically the eyesight of the inmates of the workhouse and of the Marston Green Homes in connexion with that institution It has been found that the inmates have often made the excuse of going to the eye hospital in order to obtain permission to go out, though many of them are made more comfortable by the use of glasses. Among the children many cases of defective eyesight were due to malnutrition The guardians in this respect are more progressive than the school board, which has not so far made a permanent appointment of an ophthalmic surgeon to be responsible for the testing of the eyesight of children in the elementary schools under its control.

The Hospitals

The forty second annual meeting of the supporters of the Children's Hospital was held on Feb 23rd The report showed that the number of patients during the year 1902 had been 16,761 There had been an increase in the number of operations performed to the extent of 37½ per cent. more than in the previous year As usual an adverse balance was reported and an urgent appeal was made for more funds. It was stated that one method of raising more money was started last year in the form of a fund called the "Public and Private Schools' Children's Hospital Cot Fund" in order to increase the interest taken in the work of the hospital and to add to its facilities for dealing with the many children who are brought for treatment.—The annual meeting of the subscribers to the Birmingham and Midland Skin Hospital was held on Feb 26th. The committee reported, that there were 124 in patients as compared with 157 in the previous year, the out-patients numbered 6503. An average stay of 54 days in the hospital was shown for the in patients and was taken to be an indication of the serious nature of the cases under treatment The medical report expressed satisfaction at the treatment of 103 patients suffering from lupus, cancer and cognate diseases by means of the x rays and the Finsen light, a fact which has been commented on in the public press.—The Birmingham and Midland Counties Sanatorium displayed a favourable report at the annual meeting of its supporters on Feb 27th. One suggestion of importance affecting the patients and the profession was adopted by the committee on the advice of its consulting physician—namely, the exclusion in future of consumptive patients. It was affirmed that a short stay by a consumptive patient at the sanatorium in the earlier stages of the disease did not benefit him individually, while there was a danger of other patients being infected. The decision of the committee is a matter for regret, but the committee has no doubt acted with the intention to afford the greatest good to the greatest number and has wisely supported its decision by the authority of an eminent physician.

March 3rd

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT)

University College, Liverpool The Opening of the Johnston Laboratory, the Unveiling of Dr Richard Caton's Portrait, Complimentary Dinner

THE Right Hon Walter H. Long, M.P , the President of the Local Government Board, has accepted an invitation to open the Johnston Laboratory at University College on May 9th The laboratory, which has been built and equipped by Mr William Johnston, a Liverpool shipowner, includes the following departments bio-chemistry, tropical medicine, directed by Major R. Ross, C B , F R.S , one of the Nobel prizemen of this year , and experimental medicine and comparative pathology, together with cancer research, to be conducted by Dr A. S F Grünbaum. Mr William Johnston has also endowed the professorship of bio-chemistry and three fellowships in various branches of medical research. Mr Johnston is father in law of Dr Rubert W Boyce, F R.S , the professor of pathology at University College.—On March 4th the ceremony of unveiling Dr Richard Caton's portrait took place in the Arts Theatre The portrait was painted by Mr R. E Morrison of Liverpool and was exhibited at the Liverpool autumn exhibition It is a gift to the College from Dr Caton's late colleagues on the occasion of his retirement from the medical faculty which took place in July, 1902 A replica of the portrait was presented at the same time to Dr Caton. In the evening Sir William Mitchell Banks and Dr Caton were entertained at dinner by their late colleagues and friends at the Adelphi Hotel —The annual dinner of the University College Old Students' Association will be held at the Adelphi Hotel on Saturday, March 7th, when the chair will be taken by Professor Edward Carey, the president for the year It is expected that a large gathering of former students will take advantage of the occasion to renew old friendships.

Liverpool Stanley Hospital Improved Financial Condition.

At the annual meeting of the subscribers to the Stanley Hospital, held on Feb 27th, the treasurer, in his annual report, made the satisfactory announcement that the special appeal to the generosity of the public on behalf of the heavy debit balance at the end of 1901, had met with a generous response, amounting to £5098. By means of the strictest economy the ordinary expenditure had been reduced by £400 as compared with the year 1901. There was an increase also in the subscriptions and donations of £380, but in spite of this the ordinary expenditure had exceeded the income by £820, which, coupled with provision for extraordinary expenditure, left a debit balance at the end of the year 1902 of £1068 18*s* 5*d* Corporate help was again advocated in similar terms to those expressed at the annual meetings of kindred charities.

Hospital for Women, Shaw street Critical Condition of the Finances

The support of the medical charities of Liverpool is fast becoming a burning question and if the hospitals are to be maintained in an efficient state the subscription lists will have to be considerably augmented. The reports of the treasurers of the various hospitals, the annual meetings of which have been held this year, are all gloomy in the extreme. A further wail came from the treasurer of the Hospital for Women, Shaw street. At the annual meeting of that charity on Feb 18th the accounts at the end of December, 1902, showed a deficiency of £1416 6*s* 11*d* The treasurer, in commenting on the diminishing income and increased expenditure, said that the committee would have seriously to consider the question of carrying on the hospital under present conditions Public attention was being drawn in an

There was a very large attendance. The chair was occupied by the Earl of Bandon who, as Lord Lieutenant of the county had convened the meeting Sir R. Douglas Powell (London) and Sir John William Moore (Dublin) in the most generous manner came purposely to Cork to support the movement. Both gentlemen in very powerful and impressive speeches, alluded to the terrible ravages caused by pulmonary tuberculosis, owing to which homes were made desolate and the community was robbed of some of its most useful members by a disease largely preventable. The Most Reverend Dr. Browne, Bishop of Cloyne, then proposed that a branch should be established, and in the course of his speech astonished the medical portion of the audience by showing that he had such a thorough grasp of the subject The Right Reverend Dr Meade, Bishop of Cork, proposed the formation of a general committee in a very sympathetic speech, showing his well known interest in the whole community Amongst the other speakers were Sir George Colthurst Bart , Mr Maurice Healy, ex M P , the Chairman of the Cork District Asylum , the Chairman of the Cork County Council, and Mr J Cremin. On the motion of the City High Sheriff a warm vote of thanks was passed to the Earl of Bandon for presiding His lordship in responding, referred to the pleasure which it gave him to be able to forward such a meritorious work. In the evening the medical profession of the city entertained Sir R. Douglas Powell and Sir John William Moore at dinner at the Imperial Hotel. 120 sat down to dinner, including a number of medical men from the city and county, the toasts being proposed by the chairman

Cancer in Ireland

A most important report—at least, from a statistical point of view—has just been published by the Registrar General for Ireland on cancer in that country During the year 1901 2893 deaths in Ireland were caused by cancer an increase of 176 over the previous year In Ireland in 1864 the rate of mortality from cancer was 2 7 per 10 000 living , it has steadily risen until in 1901 it reached 6 5. In 1891 the death rate from cancer in Ireland was 4 6 per 10 000 , in 1900 it had risen to 6 1 per 10,000 As to age, the period 75 years and upwards yields the highest proportion of deaths from cancer per 10 000—namely, 38 16. By far the greatest number of deaths from cancer in 1891 occurred amongst farmers and labourers. The recorded mortality varies considerably in the various counties of Ireland. It is lowest in the county of Kerry with 2 54 per 10 000, while the highest death rate is 10 47 in county Armagh. Examining more closely county Armagh it appears that the districts in which there is the highest death rate from cancer are without mountains. The two highest death rates yielded by the mortality for cancer in county Armagh occur upon quite different geological formations. To enable him to accomplish his work satisfactorily the Registrar General issued a memorandum to the local registrars throughout Ireland asking them to give particulars of any cases of death from cancer registered in their districts with the history of which they might be acquainted and which might tend to throw light on the origin of the disease and the means by which it is spread. He also invited the aid of medical practitioners in charge of several public hospitals and of several private medical friends. His request met with a most courteous response and from a close analysis of the replies received, the Registrar General states that the following are the general deductions which can be drawn —

> 1. That in many cases cancer occurs in the same family grand parents parents and other relatives of the person affected having suffered from that disease. 2. That frequently where a member of a family is afflicted with cancer other members of the family suffer from tuberculosis. 3. That in a number of instances where members of a family are afflicted with cancer other members of the family suffer from lunacy idiocy or epilepsy 4 That in some cases the disease has occurred in persons who have been in direct contact with cancer patients 5 That the disease has manifested itself in individuals who have used the tobacco pipes of persons suffering from cancer of the lip 6. That in some instances more than one case of cancer has occurred amongst different families living in the same house or amongst successive occupants of the same house 7 That in a few cases the disease has appeared in different houses in the same locality about the same time 8 That cancer not infrequently appears after wounds and injuries. 9 That in some cases cancer has supervened where there has been irritation of the lip consequent on smoking clay pipes. 10 That cancer frequently shows itself where unfavourable conditions as to residence food &c. exist.

The main practical point to be deduced from these conclusions is that something seems to be gained for the opinion that cancer is directly contagious

Death of Samuel Alexander, M.D R.U I

The death is announced at his residence, Crumlin road Belfast, after a rather prolonged illness, on Feb 25th, of Dr Samuel Alexander A native of Templepatrick, co Antrim, Dr Alexander studied at Queen's College, Belfast, and graduated M.D of the Royal University in 1885 For a time he was in practice in England, but returning to Belfast he was elected dispensary medical officer of No 5 district A careful observer an experienced accoucheur and a kind friend, Dr Alexander was greatly liked by his patients His illness was of considerable duration, and although drainage of an emphysema seemed to have relieved him he had a serious relapse, with hæmatemesis, which proved fatal He was buried on Feb 27th at the old graveyard, Templepatrick, a large concourse of friends and patients attending his funeral

Medical Men and Emergency Calls

At an inquest held in Belfast on Feb 25th as to the death of a woman suddenly from hæmorrhage from a varicose vein in the left leg it came out in evidence that the woman was dead when a medical man arrived and that another medical man who was first summoned by the husband of the deceased declined to attend as he did not go out at night. A juror was anxious to know why the medical man did not come, when the coroner pointed out that a medical man is not bound to come, but that his experience was that even if they themselves were on a sick bed they would get up and come out in an urgent case. He thought the man had not explained that his wife was in danger or else the medical man would have attended. He expressed wonder that the facilities provided in the way of ambulance were not thought of in a case where medical assistance was urgently needed.

(FROM OUR OWN CORRESPONDENT.)

The New Public Health Act

As I mentioned in my last letter the new Public Health Act came into force on Feb 19th. The Act is divided into five sections Of these, Section I contains two clauses and deals with sanitary matters in general Of the two clauses the first contains ten paragraphs dealing with general sanitary measures and the second 20 paragraphs dealing with sanitary measures applicable to buildings and the like. The points of the paragraphs dealing with sanitary matters in general are as follows. In every commune the mayor is charged with responsibility for the public health and with the duty of promulgating measures (after consultation with the municipal council and in the form of municipal by laws) for preventing or for arresting outbreaks of infectious disease. He is specially charged with the looking after of measures for the disinfection, or even the destruction, of articles used by the sick and in general terms of any article which may serve as a vehicle for the transmission of infection. These measures of destruction or of disinfection are compulsory In the same way mayors of communes are charged with drawing up regulations for the hygienic condition of houses and their outbuildings, of private roads whether thoroughfares or not, of furnished apartments, and in fact, of any mass of buildings (agglomerations) or of real property of whatever nature They are also specially charged with the care of regulations for the supply of drinking water and with the disposal of refuse of any kind. As regards these duties they will be under the authority of the prefect who, with the consent of the Departmental Council, will approve the municipal by laws or may even make them himself, *ex officio*, if the mayor will not carry out the law In cases of urgency—that is to say, in face of an epidemic or other pressing danger to public health—the prefect can order measures of disinfection or destruction to be put into being at once, and this order may apply to one person, to many or to the whole inhabitants of the commune. The list of diseases to which the sanitary regulations prescribed by the Public Health Act of February, 1902, are to be applied by means of an official schedule is still under discussion. I have previously spoken of debates upon this subject at the Academy of Medicine and also of another official regulation making it incumbent upon doctors of medicine, *officiers de santé*, and midwifes to hoped by the managers that these requirements will be supplied by the generosity of one person or by a group of subscribers The issue of a similar statement last year resulted in the presentation of a mortuary chapel by Dr O T Vachell, of a padded room for delirious patients by Mrs Mackintosh of Mackintosh, of new accident receiving wards by Mr Thomas Webb, the donor of the operating theatre, and in the installation of electric light throughout the building by the Marquis of Bute

Weston-super Mare Hospital and Dispensary

The Weston super-Mare Hospital and Dispensary was established in 1857 and has accommodation for 31 patients. The annual report of the governors states that during 1902 there were treated as in patients 260 persons and in addition to the 684 out-patients treated there were 722 accident and emergency cases attended to The financial position of the institution is said to be satisfactory

Small-pox

Swansea has been free from small-pox for several weeks and there has not been any case of the disease notified in Merthyr since the first week in January Three sailors have been removed to the Cardiff small pox hospital from a ship trading between Liverpool and Cardiff and one of the patients has since died During the past month there have been two cases at the Swansea waterworks now being constructed at Cray in Breconshire and five cases have occurred in the town of Brecon. In the Wigmore rural district there have been two cases, in Leominster four cases (one fatal), and in the city of Hereford one case. In all of the Breconshire and Herefordshire cases the source of the infection was traced to tramps. In the administrative county of Glamorgan during 1902 there were notified 172 cases of small pox distributed over 17 of the 28 urban and rural districts in the county but excluding Cardiff and Swansea. More than one half—93 cases—were notified during the last quarter of the year and 71 of these were in the town of Merthyr

University of Wales

Mr David Davies, whose grandfather was one of the founders of the town of Barry and an extensive colliery proprietor in Glamorganshire, has intimated a desire to defray the cost of erecting and fitting up new science laboratories in connexion with the Aberystwith College of the University of Wales The estimated cost is said to be about £20,000 but no definite sum has been prescribed by Mr Davies

Anthrax

The Gloucestershire county council has decided to cremate the carcasses of all animals dying from anthrax within the county and to discontinue the practice of burying them in lime

Dorset County Hospital.

On Feb 23rd, Sir Frederick Treves formally opened the new operating theatre of the Dorset County Hospital. There was a large and influential attendance at the ceremony Replying to a vote of thanks, Sir Frederick Treves delivered a short address on the advance of operative surgery The cost of the building has been defrayed by public subscriptions, including donations of £500 from Lord Eldon, £250 from Lord Ilchester, £100 from Lord Wimborne, and £50 from Lord Portman. Sir Frederick Treves presented the operating table

Bristol Hospital Sunday Fund

At a meeting of the council of the Bristol Hospital Sunday Fund held on Feb 26th it was reported that up to that date £1464 had been received and it was decided at once to distribute £1200 amongst the medical charities. This includes £522 to the Bristol Royal Infirmary, £438 to the General Hospital, £162 to the Children's Hospital, and £78 to the Eye Hospital

March 3rd.

SCOTLAND

(From our own Correspondents.)

University of Glasgow

THE graduation ceremony will take place on Tuesday, 21st April. The senate has already published the names of those upon whom it intends to confer honorary degrees Among those mentioned who are to receive the degree of doctor of laws (LL.D) are Sir William Tennant Gairdner, K.C B , emeritus professor of medicine in the University of Glasgow, and Dr Thomas Oliver, professor of physiology in the University of Durham, author of works on medical subjects embodying, *inter alia*, the results of important investigations respecting the diseases of dangerous trades.

The Glasgow Hospitals

The governing bodies of all the important hospitals in Glasgow are representing to the public the urgent necessity of raising money for extension or rebuilding The foundations of the new dispensary at the Western Infirmary have already been laid and the directors are hopeful that before long they will be able to erect and to equip a new wing to the main building The chairman of the directors of the Royal Infirmary at a dinner of the present and past residents of that institution held last week was very sanguine when he expressed his belief that within 18 months they would see the foundation stone of a new hospital laid The directors, too, of the Samaritan Hospital at their annual meeting held on Feb 25th and presided over by the Lord Provost (Mr. John Ure Primrose) made a public appeal for assistance to build and to equip the proposed new wing towards which they had already received £7000, leaving a balance of £2000 still required They had previously urged the necessity of providing an entirely new home for the nurses and they were glad to announce that a lady, who desired that her name should not be publicly known, had intimated her intention of making a gift of £8000 for the purpose of erecting such a home in memory of her late daughter This year the Glasgow Hospital Sunday Fund amounts to £5023, being above what was collected last year by £225. This money, collected by the various churches throughout the city on a particular Sunday in the year, is distributed among the three general infirmaries—the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary The Lord Provost at the annual meeting of the Samaritan Hospital suggested that this hospital should also receive a share of the fund, but this would break through a principle that has guided the committee from the outset—namely, that the fund should be reserved for the three general infirmaries. The Samaritan Hospital is only one of many special hospitals in the city and if it were to partake of the benefits of this fund it would be difficult to ignore the claims of other institutions. If they were all satisfied the money would become allocated in small amounts to many institutions and none would derive any distinct benefit

Glasgow Medical Volunteers

In spite of most inclement weather there was a very large attendance at the memorial service held in the cathedral last Saturday afternoon when a tablet was unveiled to the members of the Glasgow volunteer companies of the Royal Army Medical Corps who died in South Africa during the recent war The inscription reads This tablet is erected by the officers and men of the Royal Army Medical Corps (Volunteers), Glasgow Companies, in memory of their comrades, members of the active service section of the corps, who lost their lives during the South African campaign Corporal G G Penman, died at Bloemfontein, 12th November, 1900 , Corporal J Howat, died at Bloemfontein, 1st December, 1900 , Private W Munro drowned at Elandsfontein, 7th April, 1901 " The Director General of the Army Medical Service, Sir William Taylor, K C B., K.H.P , unveiled the tablet and delivered a brief address.

The annual dinner of the Royal Medical Society of Edinburgh was held on March 3rd, when Mr Mayo Robson was the guest of the evening Sir William Turner, Sir J Halliday Croom, Sir J Batty Tuke, M.P , Professor Chiene, and Dr William Bruce were among the 80 medical men who attended under Dr A B Ross's presidency to do honour to the guest of the evening

(From our own Correspondents.)

Establishment of a Branch of the National Association for the Prevention of Consumption in Cork.—Complimentary Dinner to Sir R. Douglas Powell and Sir John William Moore.

ON Feb 28th a very important meeting was held in the Cork Court-house for the purpose of establishing a local branch of the Association for the Prevention of Consumption.

Coal Famine and Mortality

The *department of health in Chicago considers that the* ncreased mortality for January was due directly to the shortge of coal. Unrevised returns of mortality for the month of January, 1903, show an increase of 10 per cent, (or 344) in the actual number of deaths from all causes and at all ages, and of 11 4 per cent in proportion to population, as compared with January, 1902, when coal was abundant at one-half the price or even less than it now commands—when it can be obtained at all. These two facts are cited together because, in the judgment of the health department, the latter is the principal, if not the sole cause of the former A large proportion of the excess of deaths is due to cold and exposure caused by the coal famine which at the time of the previous report (Jan. 10th) had affected the health of fully 10 per cent., or nearly 200,000, of the population of the city Had any other one cause so seriously menaced the public health and welfare a grave emergency would have been declared to exist, authorising the exercise of the plenary power of the municipality under the warrant and law of 'overruling necessity"

Injured Seamen must be taken into Port for Surgical Treatment

A United States circuit court of appeals has held in the case of the *Iroquois* that it was the duty of the master of that vessel to bear away to some port of distress as soon as possible after one of its seamen had without fault of his own or fault of the ship sustained a fracture of two ribs and both bones of his right leg below the knee. The vessel was at the time of the accident a few miles to the southward of Cape Horn. The master whose only knowledge as to the treatment of fractures had been derived from his own experience some time previously when he had received treatment from a surgeon for a fractured leg, set the seaman's leg as well as he could, bound it, and placed it upon a cushion in order to elevate it above the body, and instructed the steward to give the injured man gruel, mush, and other light food. The broken ribs healed, but the bones of the leg failed to unite, and after the vessel reached San Francisco the leg had to be amputated a little below the knee The court held that it was no excuse that the master was ignorant or that he believed that the broken leg was healing properly and that for that reason he thought it unnecessary to bear away from his course. Nor was he excused by the fact that the injured seaman at the time made no complaint of the treatment he had received and made no demand to be taken to a port of distress The duty of the master to him was a positive one. He had been disabled while in the service of the ship and without any fault on his part. By the maritime law he was entitled to be healed at the expense of the ship His injury was a serious one and the master must be presumed to have known that it required careful and scientific treatment.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT)

Proposed Amendment of the Poisons Act New South Wales

A PRIVATE Bill has been introduced into the Legislative Assembly of New South Wales to amend the Poisons Act, with the object of removing the present restrictions on the sale of proprietary medicines containing poisonous ingredients A deputation from the Chamber of Manufacturers waited on the Ministry to oppose the Bill It was stated that about 600 proprietary medicines were offered for sale in the State, of which the majority were innocuous, but some 14 contained active poisons, and if the Bill passed these could be sold without any restriction whatever

Faith Healing

The deputy coroner for Sydney (Dr R H. Todd) conducted an inquiry concerning the death of a married woman named Johnston who died in peculiar circumstances The deceased and her husband belonged to the Christian Catholic Churchd or the "People of Zion, a sect the members of which believe in healing by prayer and faith. She was attended in labour by a nurse and in the evening of the same day she became weak. The pastor of the church was sent for and he prayed over her On the next day she was worse and the nurse said that a medical man must be sent for Mrs. Johnston refused to see a medical man and a deacon of the church prayed over her all night. The nurse on her own responsibility took Dr Thomas to see the case but the woman refused to see him. Dr Thomas told the husband that the case was dangerous and that if anything happened to his wife he would get into trouble The husband replied that he did not think so and he added "We belong to a church which does not believe in doctors but believes God will take care of us." On the next day the husband brought Dr Wood to see his wife, but when he got to the house the woman was dead. The husband said that he wanted the medical man to see his wife so as to avoid an inquest Dr Wood was of opinion that Mrs. Johnston had died from loss of blood and shock from want of skilled treatment. Dr Sydney Jamieson made a post-mortem examination and found that the uterus was inverted and that death was due to hæmorrhage and shock, he thought that if medical assistance had been given the woman's life could probably have been saved, 'Parson" McCullagh, the pastor of the church, stated that if a person of their faith had bleeding from a divided artery the proper course would be to pray and not to take measures to stop the bleeding The jury returned a verdict to the effect that Johnston was responsible for the death of his wife in not insisting upon a medical man attending her when made aware by the nurse and Dr Thomas of her serious condition and Johnston was committed for trial on a charge of manslaughter

Infants Protection Bill

Dr Mackellar has introduced into the Legislative Council of New South Wales a Bill to make further and better provision for the protection maintenance, and care of infants to provide for the inspection, supervision, and control of places established or used for their reception and care and to constitute children's courts The Bill is intended to make provision for cases outside the scope of the State Children's Relief Act and deals chiefly with the question of illegitimacy The measure provides for fixing the paternity of the child before birth and where the paternity is fixed the court may require the putative father to find sureties for the payment of the expenses incurred by the mother at the birth In cases where the natural guardians of the woman, say the father and mother in such circumstances fail to give her the assistance which she has a right to expect she may apply to the State Children's Relief Board, which after inquiry may make a complaint to a justice, who will then summon the offender or offenders to show cause why they should not be ordered to support the woman and the child. The putative father will be required by the Bill to pay all the expenses of the mother during her confinement and also to provide for her for a period of six months afterwards. It is further provided that there shall be control over places for the reception of infants by way of inspection and the granting of licences at the discretion of the Minister. The Bill also contemplates the establishment of children's courts, apart from ordinary courts of petty sessions, in order that children may not be brought into contact with the associations of these establishments In moving the second reading of the Bill Dr Mackellar stated that the illegitimate birth rate in New South Wales was very high and that it had nearly doubled in the last 20 years. At present the illegitimate birth rate for the city of Sydney and suburbs was 10 per cent of the whole birth rate while in the country districts it was something more than 5 per cent., the rate for the State altogether being about 7 per cent. This was a much larger percentage of illegitimate births than prevailed in any of the neighbouring States while it was much larger than that of the United Kingdom, and he was sorry to say that the majority of the children were born of women who were immature, those who had not reached the age of 20 years.

A Disputed Insurance Policy Suicide by Prussic Acid or Accidental Poisoning by Coal Gas?

An action was recently tried in Melbourne which presented some interesting medical features. The executors of the late J E. Hoogkleimmer claimed £1000 from the New Zealand Accident Insurance Company the amount of an accident policy issued to him. Hoogkleimmer was found dead in his room apparently suffocated by an escape of coal gas The insurance company declined to pay on the ground that he had really committed suicide by taking cyanide of potassium and that the escape of gas was purposeful. An analysis of the stomach of the deceased man showed that it contained nearly half a grain of cyanide of potassium. Dr C J Martin, F R.S professor of physiology in the University of notify every case of infectious disease.[1] As regards sanitary measures in general Clause 1 of Section I. of the Act deals with those to be taken when an epidemic breaks out in any part of the Republic, it lays down rules for the action of the prefect in cases where for three consecutive years the death rate shall have exceeded the mean death rate for the whole of France, it provides him with a method for neutralising the carelessness (*moyen de passer outre à l'incurie*) of municipalities who have neglected to see that their communes have a proper supply of drinking water or who have omitted to supply a thorough drainage system. It also lays down rules for the protection of the gathering grounds of a water supply and establishes a zone of protection against pollution around them. Finally, the clause makes vaccination obligatory during the first year of life and revaccination during the eleventh and twenty first years Parents and guardians are personally responsible for these measures being carried out and this responsibility is a very real one, neglect of it leading to legal process with a penalty attached Clause 2 of Section I. deals with sanitary measures applicable to houses and the like Under this clause the erection of any building in a town of 20,000 inhabitants or more is forbidden unless a permit has been obtained from the mayor approving the plans from a hygienic point of view When a property, whether a building or not, and whether adjoining the public highway or not, is dangerous to the health of the occupants or the neighbours, Clause 2 lays down regulations whereby the mayor, or failing him the prefect, can order either that necessary work shall be done or that the building shall be closed By this clause also, windows or doors made in the interests of sanitation are exempt for a period of five years from paying the window and door tax Finally, the clause states the conditions upon which leases are to be cancelled or the compensation to be paid to the owner in case of the building being closed Section II. of the Act is concerned with sanitary administration. Under it is created a bureau of public health in towns having more than 20 000 inhabitants and in all communes of less than 2000 inhabitants, if they are thermal stations This public health bureau is a municipal body charged under the authority of the mayor with the application of the Public Health Act At Paris it has just been put into force by an order of M Selves As regards Paris a distinction is made between the duties appertaining to the Prefect of the Seine and those of the Prefect of Police. The first mentioned of these officials deals with everything relating (1) to the hygienic condition of dwelling houses and their appurtenances, with the exception, however, of premises let as furnished apartments, (2) to the hygienic condition of private roads, whether thoroughfares or not, (3) to the collection and distribution of water supplies, and (4) to disinfection, vaccination, and the removal of patients. In case of necessity he gives effect to requisitions made to him by the prefect of police He appoints an unhealthy dwellings commission composed of 30 members 15 of whom are nominated by the municipal council The duties assigned to the prefect of police are as follows (1) to take precautions for the prevention and arrest of epidemic diseases, (2) to receive notifications of these diseases, (3) to deal with contraventions of the statutes relating to vaccination and revaccination, (4) to undertake the sanitary inspection of premises let as furnished apartments and the protection of young infants, (5) to enforce sanitary regulations relating to domestic animals, (6) to enforce regulations relating to the practice of medicine and pharmacy, (7) to enforce the laws and enactments relating to the sale or exposure for sale of articles of food, either adulterated or putrid, (8) to exercise a certain supervision in connexion with the municipal laboratory, and (9) to enforce rules for the carrying on of dangerous or offensive occupations. He is assisted by the Conseil d'Hygiène et de Salubrité de la Seine the composition of which remains unaltered The same section defines the duties of the departmental Conseils d'Hygiène and of the Comité Consultatif d Hygiène de France Section III. provides for the expenses rendered necessary by the new Act, while Section V provides for certain temporary requirements. Section IV is a penal section dealing with contraventions of the provisions of the law and the penalties under this section vary from a fine of 16 francs to one of 1000 francs As I have already mentioned, the Prefect of the Seine has issued an order dealing with the duties imposed upon the Paris Bureaux d'Hygiène. This order concludes as follows "The public bodies appointed under the direction of the municipal authorities for the protection of the public health take the name of Bureaux d'Hygiène de la Ville de Paris (Préfecture de la Seine) in conformity with Section XIX., Clause 2, of the Act of Feb 19th, 1902."

The Question of Fœticide

On Feb 9th the Medico-Legal Society unanimously adopted the report of M Maygrier on the question of fœticide The conclusions of the report are as follows —

1 The medical man incurs no responsibility except under the terms of the Common Law (Articles 1382 and 1383 of the Civil Code)—excluding that is to say cases in which he may be reasonably accused of imprudence or of negligence altogether outside the scientific aspect of the case.

2. The medical man should never operate against the expressed wish of a patient in full possession of her faculties There may be cases, however in which owing to some unforeseen emergency the medical man will be compelled by his sense of duty to operate when the patient has not given her consent.

3 In the case of an unconscious patient the same general rules apply in so far as regards persons having authority over her cases of urgency and of unforeseen complications, which may be very numerous being excepted

4 In no case should the medical man having proposed one operation substitute another wished for either by the patient herself or by persons having legal authority over her if he considers such operation either dangerous or inopportune The refusal to accept his services under conditions laid down by himself releases him from all responsibility whatever may be the consequences Humanity alone gives him the right to interfere

March 3rd

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

New Army General Hospital.

THE Secretary of War is about to establish in the District of Columbia a hospital which shall serve as a base in time of war and shall be so situated and designed as to make immediate and temporary enlargement possible On the outbreak of war such a hospital would immediately be needed because of the gathering together of troops in the vicinity of Washington. The hospital is to be part of the equipment of the army medical school, giving to the student-officers an opportunity to become familiar with the method of administration, hospital inspection, the use of the Roentgen rays and other diagnostic apparatus, and medical and surgical procedures especially employed in the military service. It is also to be equipped for the practical training of the hospital and army nursing corps. The staff is to be made up of army medical officers specially skilled in surgery and diseases of the eye, ear, throat &c., and special facilities will be provided for the treatment of such cases. During the recent war such a hospital was established at Washington barracks but it was found to be altogether too small and it cannot be enlarged because the ground is needed for other purposes. Since 1898, when this hospital was first used, 3000 hospital corps men have been trained and sent to military posts in the United States, Porto Rico, and the Philippines. The student officers have benefited by the hospital training in its branches and the Government has been saved thousands of dollars in pensions because of the successful performance of hundreds of operations for hernia.

Spread of the Plague

It is now evident that through the failure of the authorities of San Francisco to recognise the presence of the plague in that city and to take proper precautions against its spread many of the seaport towns of Mexico have been infected and the disease is spreading to the interior During the first 15 days of January 107 deaths from plague occurred at Mazatlan, Mexico, and 106 houses have been burned California and other adjoining states have sent money for relief and to furnish food The Mexican Government is trying to get control of the disease and has held an extra session of Congress for that purpose It was rumoured that the plague was present in Mexico, Guadalajara and Sonora, and in Ensenada, Lower California, and many towns in that part of Mexico are being gone over very rigidly It was, however, very emphatically denied that there was any sign of the plague there It is probable that the spread of the bubonic plague from San Francisco to Mexican cities will raise the question of the obligation of nations to prevent the spread of contagious diseases from one to another The Mexican Government is said to be preparing a claim against the Government of the United States for damages to commerce by the transmission of the plague to its cities

---

[1] THE LANCET Jan 31st 1903 p 338

Central Provinces In August, 1881, he was promoted to be brigade-surgeon On June 1st, 1883, he left India on furlough, returning to Bombay on Dec. 30th, 1884 On April 17th, 1885 he was posted as deputy-surgeon-general. In the capacity of principal medical officer at Calcutta he inspected all troops proceeding thence to Burmah for the last campaign and superintended the despatch of hospital ships and stores. In September, 1886, he retired with the rank of surgeon general after 31 years' service in India, and returning to England he lived at Brighton, Winchester, Ealing, and other places. Even in private life he retained his interest in hospital work and indulged it to some extent by acting on the committees of the Sussex County Hospital, the Hants County Hospital, and the Ealing Cottage Hospital. Surgeon General Brake was married on August 19th, 1852, to Annie, daughter of Mr John Miles Bull. He was left a widower on Dec. 23rd, 1897, and is survived by three daughters and an only son, Lieutenant-Colonel Herbert Brake, R.A., C B D S.O , at present commandant at Trinidad.

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Didiot, formerly Medical Inspector-General of the French army —Dr Lösch, formerly Professor of Medical Diagnosis in the University of Kieff.—Dr Dante Cervesato, Clinical Professor of Children's Diseases in the University of Bologna.—Dr Carlo Gallozzi, Rector of the University of Naples and one of the most eminent of Italian surgeons.

Medical News.

UNIVERSITY OF CAMBRIDGE —At the Congregation held on Feb 26th the following medical and surgical degrees were conferred —

Doctor of Medicine —A. E. Bodington, Gonville and Caius.
Bachelor of Medicine and Bachelor of Surgery —A. W Izard, Trinity E A. Ross Trinity H Wacher St John's and L B Aveling Christ's.
Bachelor of Medicine.—N F Ticehurst Clare.
Bachelor of Surgery —D Holroyde, Trinity

Dr Norman Moore, St. Catharine's, is to be one of the University delegates to the approaching International Historical Congress in Rome

FOREIGN UNIVERSITY INTELLIGENCE —*Bologna* Dr Calderone has been recognised as *privat-docent* of Dermatology —*Breslau* Dr Ludwig Krehl of Tübingen has been offered the chair of Clinical Medicine.—*Buenos Ayres* Dr Borda has been appointed Professor of Clinical Psychiatry, Dr L. Valle as Professor of Operative Medicine and Dr Delfino and Dr Uriarte Professors of Bacteriology —*Florence* Dr Arturo Banchi has been recognised as *privat docent* of Anatomy —*Gratz* Dr Max Stolz has been recognised as *privat docent* of Midwifery and Gynæcology —*Greifswald* Dr Paul Leopold Friedrich of Leipsic has been appointed to the chair of Clinical Surgery —*Munich* Dr Anton Bumm the Professor of Mental Diseases being in bad health, Dr Hans Gudden has been entrusted temporarily with the lectures on that subject.—*Rio de Janeiro* Dr E de Nascimento Silva has been appointed to the chair of Forensic Medicine and Toxicology —*St Petersburg (Military Medical Academy)* Dr W Oppel has been recognised as *privat docent* of Surgery and Dr S Lobanoff as *privat docent* of Ophthalmology —*Stockholm* Dr F Westermark has been appointed to the chair of Midwifery and Gynæcology —*Utrecht* Dr. Laméris has been recognised as *privat docent* of Surgical Diagnosis.—*Vienna* Dr Theodor Panzer has been recognised as *privat-docent* of Medical Chemistry

THE NEW HOSPITAL FOR WOMEN —On March 3rd the Bishop of London presided over a largely attended meeting of the supporters of the New Hospital for Women which was held in the board room of that institution. In moving the adoption of the thirty first annual report the Bishop referred to the interest which Her Majesty Queen Alexandra had taken in the institution and mentioned that a scheme had been prepared with the object of establishing a bed in the hospital in memory of the late Emperor and Empress Frederick. The report stated that the hospital now contained 52 beds and that the number of in patients during the year amounted to 619 The out-patients numbered 7443. The committee of management calls attention to the serious state of the hospital finances During each of the past three years the receipts have been considerably lower than the expenditure. In seconding the report Professor T. Clifford Allbutt said that excellent work was done by the institution which well deserved the support of the charitable public. The report was adopted

THE LATE EDMUND CLEAVER PETTIFER, M B LOND , M R C S ENG —Dr E C Pettifer, who died recently in Calcutta, received his medical education at St. Bartholomew's Hospital, where he gained two scholarships and the Harvey prize. In 1884 he became qualified as M R C S Eng and in 1885 he graduated as M. B at the University of London After holding the appointment of assistant house surgeon at Tewkesbury Hospital he proceeded to India where he did special sanitary work in connexion with plague at Fyzabad and Ajudhia. When plague broke out in Calcutta in 1897 he was employed by the Bengal Government as a plague officer with the appointment of assistant special health officer He afterwards became district medical officer, District II., Calcutta, and also acted for the special health officer He did much valuable work in tracing the relations existing between plague in the rat and in the human subject.

THE MEDICAL GUILD —The main objects of the Medical Guild are the organisation of the profession in order to secure united action and the common good. The annual report for 1902 shows that 16 meetings of the council have been held during the year In referring to club reform the council expresses a wish to have it made generally known "that the 2*s* 6*d* entrance fee in the Club Pledge has been waived ' and that there are several cases reported in which the minimum tariff of 4*s* per member has been obtained. The methods of the National Deposit Friendly Society are criticised. The guild has passed a resolution recommending that all practitioners who are willing to do so should vaccinate for the State, and that the cost should be defrayed by the State provided that the standard of efficiency is the same as that of the Local Government Board This recommendation, however, does not find favour with public vaccinators in general. The guild is strongly opposed to advertisements of lectures to practitioners and senior students when these advertisements appear in the lay press and give the names of the lecturers The *Medical Guild Quarterly* is the journal of the guild. There are 196 members. The president is Alderman F H Walmsley J P and the secretary is Mr David Owen, St Brelades, Irlams-o' th' Height, Manchester

BRITISH MEDICAL BENEVOLENT FUND —The annual general meeting of the subscribers to this fund was held on Feb 24th, the president, Sir William H. Broadbent, Bart., K.C V O , being in the chair The treasurer's financial statement and the report of the committee for the past year were presented and adopted. The latter stated that, owing to the falling off of subscriptions, the grant department had been a source of constant anxiety and that it had been necessary to spend a reserve of £200 which had been set aside from a legacy to meet any exceptional crisis Subscriptions amounting to £1026 19*s* 4*d* and donations amounting to £468 16*s* 2*d* had been received and the sum of £1503 10*s* had been distributed to 152 applicants in grants varying from £5 to £18 and payable in most cases by monthly instalments. In the annuity department the interest from investments had yielded an income of £2450 6*s* 7*d* and £2291 10*s* had been received by the annuitants, of whom there are now 115 The working expenses of the fund had been only just over 5 per cent. and the accounts had, as usual, been subjected to a strict investigation by chartered accountants, the audit this year having been most kindly undertaken by the well known firm of Messrs Deloitte, Dever, Griffiths, and Co. Hearty votes of thanks were accorded to the president and other officers who were unanimously re elected, and the meeting concluded with a warm acknowledgment of the support always given to the charity by the medical press

A MEDICAL FAMILY —The death at Litcham, Norfolk, on Feb 15th of Mr Henry Raven (M.R C S. Eng and L.S.A. 1839, F R.C S Eng , 1859) closes a remarkable chapter of local history His grandfather (who died in September, 1807, aged 67 years), his father (who was baptised at Litcham in May, 1765, and who died in March, 1849), and his elder brother (who died in February, 1854) have successively practised at Litcham since the middle of the eighteenth century Mr Henry Raven was born on

Melbourne, gave expert evidence as to the results of his examinations of Melbourne coal gas. He had made five analyses of samples taken during a period of ten days. The mean result was that there was 0 065 grain of hydrocyanic acid in every gallon of gas About a grain would be required to be inhaled to cause death and about the two hundredth part of a grain would then be found in the stomach. If half a grain were found in the stomach it must have got there through the mouth Dr Martin had made post-mortem examinations on men in two cases and on animals in 168 cases in which death had been brought about by hydrocyanic acid Evidence was also given that Hoogkleinmer had tried several times to insure his life but that he had failed as he had diabetes. It was found, too, that the gas bracket had been tampered with. The jury found that death was due to suicide and gave a verdict for the insurance company

The Asylum Difficulty Resignation of Dr S Macbirnie

Dr Macbirnie, the medical officer at the Metropolitan Lunatic Asylum, Melbourne, who was charged with misconduct and was acquitted, has resigned. No steps have yet been taken to fill the position caused by the dismissal of Mr W Beattie Smith and the resignation of Dr Macbirnie and the department will probably find some difficulty in the matter

Obituary

Great regret was felt at the death, on Dec 26th, 1902, of Dr E Fairfax Ross at his residence, Macquarie street Sydney, at the early age of 45 years Dr Ross was educated in Goulburn, New South Wales, but went to London for his medical course, being a student at University College He took the M R C S Eng and L R C P Lond. in 1884 and later the M D of Brussels. He was house physician at University College Hospital to Dr Wilson Fox. On his return to Sydney he soon took a leading position He was senior physician to St Vincent's Hospital and was also surgeon to the Lewisham Hospital for Women and Children. He had a large practice and his kindly sympathetic nature endeared him to his patients and friends. He has left a widow and three sons. —By the death of Dr Emma Constance Stone-Jones Melbourne loses the pioneer woman physician in Australia. She was born in Hobart in 1854 She early evinced scientific tastes inherited from her father who was a biological student She studied anatomy and then decided to pursue a medical course. There was at that time no opportunity of doing so in Australia—in fact, the idea was almost unheard of She went to Philadelphia and entered at the Woman's Medical College After a few years she proceeded to Toronto where she graduated as M D in 1888 In the following year she studied in London and took the L S A. In 1890 she returned to Melbourne and commenced to practise in Collins-street In spite of old fashioned prejudices she soon acquired a large practice and her success encouraged other young women to study medicine when the Melbourne University was thrown open to them. She was practically the founder of the Queen Victoria Hospital for Women Her zeal and ability enabled her to take a high position in the profession and she was held in the greatest esteem by all its members She married the Rev D Egryn Jones, M D, and had one child Her health had been failing for some years before her death from tuberculosis It is, perhaps significant that in Melbourne out of a not large number of women practitioners three already have died—Dr Castilla, Dr O'Hara, and Dr Stone-Jones—and three have given up practice after marriage.—Dr Richard James Quinnell, late brigade surgeon in the Indian Medical Service, who died recently, was 68 years of age and had practised for some years in South Yarra Victoria.—Dr Charles W Pardey died in Sydney where he was medical officer to the District Medical Institute. He graduated as M B at the University of Melbourne in 1883 and was for some time senior house surgeon at the Sydney Hospital

Jan. 14th.

EXETER DISPENSARY —The annual meeting of the subscribers to the Exeter Dispensary was held on Feb 24th. The medical report stated that 5642 patients were treated during 1902 as compared with 5638 in 1901 The financial statement showed that there was a favourable balance of £300 and that the invested capital of the institution at present amounted to £17,301.

Obituary.

JOHN BRAKE, M R C S ENG, L S A,

SURGEON-GENERAL INDIAN MEDICAL SERVICE (RETIRED)

Surgeon-General Brake, who died on Feb 8th at "San Remo," Craneswater park, Southsea, was a man of decided abilities which would, without much doubt, have enabled him to attain a good position in any branch of medicine He was born on Dec. 6th, 1827, his father being Commander William Lenthal Brake, R N His early education was received at the City of London School under Dr. Gyles and Dr Mortimer, he was an apt pupil and made such progress in the various classes that on eventually matriculating at the University of London he passed with honours in mathematics In 1850 he entered as a student at St. Thomas's Hospital, where his proficiency in anatomy and chemistry obtained for him a scholarship tenable for three years, he also gained prizes for anatomy, physiology, forensic medicine, midwifery, and clinical reports, as well as six first certificates of honour, a dressership, and a clinical clerkship In 1853 he took the diplomas of M R C S Eng and L S A. He therefore commenced professional life with every prospect of success and decided to take advantage of the opportunity which presented itself when the East India Company introduced the system of competitive examinations for admission to its medical service. The first of these examinations was held in England on Jan 24th, 1854, Mr. Brake came out high on the list of successful candidates and received a commission as assistant surgeon In selecting a presidency in which to serve he chose Bengal, he arrived in Calcutta on June 13th, 1855, and was at first appointed to H.M. 35th Regiment He afterwards served successively with the company's 3rd European Regiment 8th and 81st Regiments, and the 4th Battalion Bengal Artillery The year 1857 is memorable for the outbreak of the great mutiny of the sepoys in the company's army Mr Brake was then first garrison assistant surgeon at Lahore and was engaged in the first disarmament there at the commencement of the mutiny in May of that year He was then posted to the medical charge of the 7th Punjab Native Infantry on its formation in August, 1857, and proceeded with a wing of the regiment in additional charge of Brigadier General Nicholson's staff and No 17 Field Battery to the camp before Delhi, also in August, 1857 He afterwards had as an additional charge the detail hospital for wounded at Meerut On Dec 6th he was recalled to Lahore and posted to the newly raised 2nd Sikh Cavalry He accompanied the force by which General Sir John Lawrence, the Governor General, was escorted to Delhi, where he had the additional charge of civil surgeon and medical charge of the Mogul king and his family when prisoners He was also attached to the 8th and 9th Police Battalions, Police Rissallah headquarters 4th Irregular Cavalry, and 23rd Punjab Infantry In 1858, while in medical charge of the 2nd Sikh Cavalry he accompanied Brigadier Colin Troup's column in Oudh and Rohilcund and in pursuit of Ferozeshah He was with General Whitlock's field force from Feb 1st to April 11th, 1859, was in medical charge of Captain Wright's column, and was present at the fight at Imlipani on March 29th For his services he was now mentioned in despatches. He was with General F Wheeler's force in Bhundelkund from Oct 13th to the end of the campaign, was in medical charge of Captain Wright's column till Dec. 5th, 1859, and was mentioned in despatches (not published) by General Wheeler He received the special thanks of the Government for attending to the wounded under a heavy fire He was also awarded the Mutiny medal. In 1862 he was appointed to joint medical charge in Simla and in 1864 was appointed by the Governor General as first superintendent of vaccination in the Central Provinces. In 1867 he was promoted to be surgeon major On Oct. 31st, 1867, he was appointed superintendent-general of vaccination in the Central Provinces and Hyderabad Assigned Districts In February, 1870, he was appointed inspector general of prisons in the Central Provinces. He had several times officiated as sanitary commissioner in the Central Provinces and in November, 1877, he definitely received this appointment. In December, 1878, he became civil surgeon and principal of the medical school at Nagpur, this being the most important medical charge in the

ıtral Provinces In August, 1881, he was promoted
be brigade-surgeon. On June 1st, 1883, he left
ha on furlough, returning to Bombay on Dec. 30th,
4 On April 17th, 1885, he was posted as deputy
geon general. In the capacity of principal medic
cer at Calcutta he inspected all troops proceeding th
Burmah for the last campaign and superintend he was now
spatch of hospital ships and stores. In Septemb of cancer in

WEDNESDAY MARCH 4TH

Small pox in Staffordshire.

r No OGHILL asked the President of the Local Government Board if
nivers state the number of cases of small pox that had occurred in
nical *fordshire potteries during* the present outbreak what hospital
odation had been provided for them and if there had been
FO ercrowding of small pox patients.—Mr LONG replied Accord
r C the information in my possession there were during the first
onths of this year 59 cases of small-pox in the district referred,
ermang a *population of 262,500* The *local* authority for providing
as be ox hospital accommodation is the North Staffordshire Joint
yres al Board The Joint Board has only been recently constituted
has made temporary arrangements *for* accommodating small
linic ases and is treating the patients in some temporary iron
ledic ons. My attention has been called *to* statements in the local
lacte alleging overcrowding in the hospital and I have directed one of
edical inspectors of the department to visit the district and to
ogn t on the subject.
as ?

Renewal of the Vaccination Act.

olor COGHILL asked the First *Lord of* the Treasury if he would say
as t course the Government proposed to take on the expiration of the
ılu ent Vaccination Act and whether legislation would be proposed this
ion to make revaccination generally compulsory —Mr BALFOUR
eplied : My right hon. friend the President of the Local Government
ard propo es to renew the existing Act this year and to defer any
rther legislation on the subject until a future session —Mr COGHILL
ll it only be renewed for one year ?—Mr BALFOUR Without
solutely pledging *myself* that is perhaps the most convenient course.
Mr GALLOWAY : May I ask whether the Act will be included in
Expiring Laws Continuance Bill ?—Mr BALFOUR : That is a
estion I would not like to pronounce upon but it is a small matter
Ir COGHILL : Is the right hon. gentleman aware that serious out-
aks of small-pox are tak*ing place in large* towns like Manchester and
rpool ? May I ask that this should be considered ?—Mr BALFOUR
is not aware of that. Perhaps the hon gentleman will put down a
stion

THE LATE GEORGE CHARLES HENRY WIGAN, M D, C M ABERD, M R C S ENG, L S A—The funeral of Dr G C H. Wigan took place in the Portishead parish churchyard on Feb 21st Dr Wigan was born in Tippoo Sahib s Palace at Seringapatam, which had been converted into a military depôt his father, Colonel Wigan, being in command. He studied medicine at St George s Hospital and became qualified as M R C S Eng and L S A. in 1843 and 1841 respectively He graduated as M D and C M. at Aberdeen University in 1864 Dr Wigan at first practised in London, but his health breaking down he went to Australia and was on the honorary staff of the Maitland Hospital, New South Wales After remaining there for ten years he returned to England and commenced practice at Portishead. The deceased, who was in his eighty third year, has left three sons and four daughters, all of the former being members of the medical profession.

THE HOUSING QUESTION IN ANGEL MEADOW, MANCHESTER.—It often happens that such names as Paradise square, Angel Meadow, &c, indicate places by no means suggestive of Paradise, and certainly not occupied by angels of the better sort. Angel Meadow in Manchester, for instance, is in a ward, perhaps the poorest and most insanitary in the city, which has the angelic title of St Michael's ward It rarely happens that the dwellers in the slums complain of insanitary and unsavoury surroundings. Indeed, one of the difficulties often met with by the sanitary committee in dealing with unhealthy property has been the tenacity with which the occupants cling to their wretched tenements. But a large number of these people think that they have a grievance against the corporation, in that "while a great deal of insanitary property has been destroyed of late years nothing has been done to rehouse the dispossessed tenants," with the result that there is much overcrowding in the district They contend that the new workmen's houses at Blackley are useless to them, because "the rents are much too high for the poorly paid labourers and the distance from the centre of the city is viewed with great disfavour by the people"—i.e, they are too far from the work of the city Meetings have taken place in the ward, one was held in the St. Michael's Schools recently at which a resolution was passed condemning the corporation for destroying large numbers of houses and rendering their inhabitants homeless without providing other dwellings. The council was urged to buy the waste land in the district which, it is said, is sufficient to allow of 200 or 300 houses being built on it. It is no doubt a healthy sign for the people to wake up to what they suffer from unhealthy surroundings but the housing difficulty is not to be easily solved If the corporation is a buyer of land up goes its price The high price of bricks and all building materials, the artificial raising of the price of labour by trade-unions the prevalence of the 'ca' canny" style of labour, leading to the work done being brought down to the smallest amount that can with any pretence of decency be allowed to pass, and that work often badly done, all tend to make it almost impossible for the corporation to build houses at a rent which the lowest class of the working people can pay In the district in question a large proportion of the inhabitants are market labourers, whose wages vary from perhaps 12*s* a week in winter to 30*s* in the height of summer They cannot, therefore, live far away from their work. But beside the difficulties arising from dear materials and dear labour, there is another in the fact that the land round about Angel Meadow is very costly from the increased demand for warehouses The working classes themselves are, no doubt, in part at any rate to blame for this dilemma. One curious fact is that with regard to some of their plans for cottage building the corporation has been blamed for not coming up to the standard of its own building by laws, in order, of course, to bring down the cost. If the rents, to pay a modest return, are too high for tenants to pay, are they to be lowered and the ratepayers to be mulcted to make up the

Lunacy in Ireland

Mr CLANCY asked the Chief Secretary to the Lord Lieutenant Ireland whether in view of the increase in lunatic asylum charge Ireland in recent years he would consider the expediency of app ing a select committee to inquire into the cause or causes of growth of local expenditure on lunatic asylums in that country to consider whether any means could be found of limiting or reduc the burden on Irish ratepayers which was involved —Mr WYNDH replied The statistics of insanity do most unfortunately show increase in the numbers of the registered insane This increase is confined to Ireland There has necessarily been a correspondin expansion in the contributions from local rates and from Parli mentary grants for the provision of accommodation for the insane a for their maintenance The proposal in the question has already bee dealt with in the reports of the Royal Commission on Local Taxatio and I see no reason for further investigation

The Form of Medical Certificates

Mr WEIR asked the Lord Advocate whether the Secretary fo Scotland was aware that some school boards in the Highland croftin counties insist on prescribing the precise form in which a medic officer shall make out his certificate, notwithstanding the fact th no such powers are conferred on school boards by Act of Parliament and seeing that two crofters in the Western Highlands were recentl prosecuted and fined for not sending their children to school, t medical certificates with which they had provided themselves n being accepted by the chairman of the school board on the groun that the medical officer did not subscribe the words on soul and co science after his signature would he consider the expediency of issuin a circular to school managers on the subject —The SOLICITOR GENER for SCOTLAND on behalf of the Lord Advocate, replied The honourab Member has already been in communication with the department o this subject The rejection of the certificate was by the sheriff a the honourable Member has been informed that it does not fall withi the province of the department to review the decision of a court law The suggestion contained in the latter part of the honourab

Notes, Short Comments, and Answers to Correspondents

THE NOTTINGHAM HOSPITAL FOR CHILDREN

TTERS at the Nottingham Hospital for Children *do not seem to* e in a very satisfactory condition The last two house surgeons ave resigned and the crux of the *question* would appear to e in the influence exercised by the lady superintendent In HE LANCET of Sept 13th, 1902, *p* 784 we published a letter om the then house surgeon Dr James Campbell, wherein e quoted a resolution passed a fortnight previously by the oard of management to the following effect: That the dy superintendent be given to understand in cases which she elieves the house surgeon is not properly carrying out the instructions of the honorary medical staff that it is her duty to report ach case at once to the board through the chairman." Dr ampbell resigned his post at about this date *for in the same issue* f THE LANCET appeared the announcement that the post of house urgeon to the Nottingham Hospital for Children was vacant. Mr F Gaitskell thereupon applied for the post and was elected o it He made inquiries about the above-mentioned by law nd was informed by the chairman that it had been rescinded Ir Gaitskell said that he would accept the post on condition that e was in no way interfered with by the lady superintendent To his the board of management agreed and Mr Gaitskell entered on is duties

About the end of January 1903 scarlet fever broke out in the ospital and two patients were removed to the fever hospital our or five days later Mr Gaitskell heard one nurse say to her ompanion that another nurse was ill and had been ill *for some* hree days. Mr Gaitskell mentioned this fact to one of the onorary medical staff and he mentioned it to the lady superintendent She in her *turn* asked Mr Gaitskell to see the patient and added that it was his duty to know if any nurse were ill and to apply to herself as to a time to see the patient Mr Gaitskell examined the nurse and considered her to be suffering from scarlet fever On the following day one of the honorary medical staff confirmed *this diagnosis* the case was notified and the patient was removed to the fever hospital. About a week later the chairman at a board meeting asked Mr Gaitskell *why* he *had* sent a nurse to the fever hospital who had not got scarlet *fever at all* To this Mr Gaitskell said that it was the first that he had heard of the matter and asked the chairman to tell him *from whom* he derived his information To this the chairman replied that he did not know but that he would find out Apparently the information *came* from the patient herself On Feb 11th Dr L W Marshall requested Mr Gaitskell to see the lady dispenser with a view *of* finding out whether she were *physically* fit to perform her duties Mr Gaitskell saw the dispenser (Miss Rose) and came *to* the conclusion that she was recovering from a cold that her temperature was normal and that she was fit to discharge *her duties* On Feb 12th Dr Marshall informed Mr Gaitskell that he had just seen Miss Rose who told him that she had been *dismissed by the* lady superintendent as being not well enough to perform her duties Mr Gaitskell saw the lady superintendent who said that as Miss Rose was not well she had engaged another dispenser Mr Gaitskell answered that as he had seen the dispenser and had come to the conclusion that she was physically fit he considered that the lady superintendent had interfered in a medical matter and that he should bring the question before the board That same evening Mr Gaitskell received a letter from the chairman which began:

Seeing that Miss Rose is not well I consider that Miss Ducane (the lady superintendent) is justified in finding another lady to act as dispenser " Mr Gaitskell *replied* that the chairman seemed to be under a misapprehension and that the lady was not ill, and, further that he considered it his duty to keep Miss Rose in her post until he heard from the chairman again. The chairman answered that as Miss Rose had only been appointed temporarily for ten days and had held the post for three weeks he therefore appointed Miss King *in her* place Mr Gaitskell replied that he bowed to the chairman's ruling but that he objected to the lady superintendent interfering in a medical matter On Feb. 20th a *special* meeting of the board was held in which a letter from the chairman was read stating that he had heard from several influential gentlemen in the town that Miss Ducane had been insulted by Mr Gaitskell Letters were read from sisters and nurses, with whom Mr Gaitskell allowed that he had *found fault* endorsing the complaint

Finally Mr Gaitskell was informed that a motion had been passed but not unanimously that he should apologise to the chairman for his conduct Mr Gaitskell refused *to* apologise alleging that he had only answered as he considered it his duty to that the chairman had acted in a medical matter on the authority of the lady superintendent without *consulting him* and that he then and there wished to resign

We have written the above upon Mr Gaitskell's statement fortified by letters and a copy *of* the by laws.

By law No 10 of those concerning the house surgeon states that the nursing staff and the servants shall be medically in the care of the house surgeon " It appears to us that the lady superintendent was exceeding her duties in dismissing the dispenser as ill when the house surgeon said that she was well. We have no wish to hold up house surgeons as infallible, but any house surgeon presumably knows better whether a patient is well or ill than does a lady superintendent even if she be a fully trained nurse which by law 1 of those dealing with the lady superintendent says that she shall be Mr Gaitskell was educated at Guy's Hospital and took the diploma of M.R.C S Eng L.R.C P Lond. It would be interesting to know where Miss Ducane was trained and for how long We think, more*over* that the members of the committee of management would be well advised if they took steps to remedy an obviously unsatisfactory state of things

UNFORTUNATE ADVERTISEMENT

To the Editors of THE LANCET

SIRS —Some kind friend has sent you a cutting from a paper containing an advertisement of Earl's pepsine of which article my recommendation is given I did not notice the advertisement in question but long ago I requested that my report on Earl's pepsine should be discontinued I have now stated that if it were not I should *apply for an* injunction to restrain its publication. I gave the report in question about 30 years ago before I was a Fellow of the College of Surgeons and whilst I was practising exclusively as an analytical chemist. I never got a fee for it but, on the contrary pecuniarily assisted the proprietor of the drug to manufacture it, as I felt interested in him It is the only drug I have ever made a report on for trade purposes Years after my report many of the leading physicians of Dublin gave laudatory certificates of the efficacy *of* this pepsine and I believe that their certificates are still made use of judging by the circular of which I inclose a copy and which has only just come into my possession

Your obedient servant,

Dublin, March 2nd, 1903 CHARLES A CAMERON

*** The circular inclosed by Sir Charles Cameron contains 18 so-called medical reports" from various *practitioners.* We observe among the signatories of these no less than seven ex-presidents of the Royal College of Surgeons in Ireland. We *think* that any of these gentlemen who are still alive should follow Sir Charles Cameron's example and insist *through their solicitors on the* suppression of their medical reports "—ED L

A WARNING

To the Editors of THE LANCET

SIRS —In reference to the letter published in THE LANCET of Feb *28th* p 628 headed "A Warning" it will interest Dr W K. Sibley and others to know that the German giving the name of Dr Richard Osten of Berlin and the London Hospital was arrested in my presence on Sunday evening Feb 22nd having succeeded in obtaining *further sums of money under false* pretences from two of my acquaintances He was brought up before the magistrate the following morning and remanded *one* week *for* inquiries so that by this time probably he has realised the penalty of his depredations

I am, Sirs yours faithfully

Harley-street W March 3rd 1903 J H. STOWERS

WANTED—A SANATORIUM.

To the Editors of THE LANCET

SIRS —Is there any sanatorium where a domestic servant can be sent with early tuberculous phthisis *for open-air* treatment and what is the cost?

I am Sirs yours faithfully

March 3rd 1903.

ENQUIRERS.

*** There are as yet very few institutions save those that serve local needs where such a case could be taken at any greatly reduced rates —ED L.

THE DEATH OF MISS ELLEN MARY SHARP M.B LOND

THE death of Miss Ellen Mary Sharp, *M.B Lond* a very able young member of our profession, took place at the Victoria Hospital Hull, last month in sad circumstances Miss Sharp was senior house surgeon at the hospital and was taken ill on the last day of January her symptoms pointing to influenza. In *spite of regular* and devoted attention in the hospital pneumonia supervened with fatal result on the tenth day of illness. At the close of her illness Miss Sharp was seen by Dr Cavendish Molson a homœopathic physician sent to the hospital by her father with instructions *to take entire charge of* the case which he appears to have attempted to do upon eclectic" and bio-chemical" principles of which the exhibition of *one-billionth* of a grain of common salt may be taken as an example if the newspaper report which has reached us may be taken as correct Miss Sharp's death was made the subject of a post mortem inquiry when the *father* of the deceased lady wrote a strong letter to the coroner alleging neglect and ill treatment against the staff of the hospital on several counts The allegations were categorically contradicted by many witnesses. The assistant house surgeon proved that Miss Sharp was in accordance with her own desire from the beginning of her illness under the care *of the assistant* physician to the hospital, Miss M. C Murdoch whose instructions were faithfully carried out Miss Murdoch described Miss Sharp's illness from day to day and gave an extraordinary account of Dr Molson's intervention and of his theory of treatment by bio-chemistry It appears that in his chemical practice microscopical doses of salts are administered to

Jefferson Medical College Hospital. Second edition revised and largely re-written. Vol. I. Remedial Measures other than Drugs, Prescribing, Preventive Medicine, Treatment of Diathetic and Nutritive Diseases. Vol. II. The Treatment of Fevers and of the Respiratory, Circulatory, Digestive, Renal and Nervous Systems and Skin Diseases. Vol. III. EDITORIAL NOTICES

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed clusively 'TO THE EDITORS,' and not in any case to any entleman who may be supposed to be connected with the ditorial staff. It is urgently necessary that attention be iven to this notice.

t is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

ectures original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

etters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. II. of 1902, which was completed with the issue of Dec 27th, and the Title-page to the Volume, were given in THE LANCET of Jan. 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months ...	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER. THE LANCET OFFICES, 423, STRAND LONDON ENGLAND.

During the week marked copies of the following newspapers have been received *Altrincham and Bowdon Guardian Yorkshire Post, Westminster Gazette Warrington Guardian, Sussex Daily News Colchester Gazette Belfast News Letter Birmingham Post, Aberdeen Free Press (Weekly) Brighton Gazette Surrey Advertiser Bristol Mercury Derby and County News Dublin Express Bradford Observer Morning Post Hereford Mercury Daily Graphic Sanitary Record Local Government Chronicle Mining Journal Hertfordshire Mercury Walsall Observer Halifax Evening Courier Scotsman &c*

the patient upon analogy because plants receive microscopical doses of salts from the soil Evidence was given to show that Dr Molson's treatment helped the unfortunate patient down the hill but it seems probable that when bio-chemistry was given a trial the inevitable end was near The coroner in summing up made some very strong remarks upon the attitude taken by the father in slandering the hospital He considered that Dr Molson must have told Mr Sharp that his daughter had been wrongfully treated and that Dr Molson was to be blamed The jury brought in a verdict of death from natural causes and in exonerating the hospital staff from all blame expressed their opinion that Mr Sharp and Dr Molson should have been present at the inquest and should be strongly censured

We do not want to add to Mr Sharp's grief at the loss of his accomplished daughter but we must endorse the view of the jury that his attitude was reprehensible. We presume as the coroner seems to have presumed that Dr Molson gave an unfavourable account of the treatment that Miss Sharp received before he attempted to arrest death by a display of bio-chemistry Mr Sharp certainly should have obtained genuine evidence against the hospital authorities before he committed himself to gross accusations against them in a letter to the coroner Had he made the least inquiry he would have found his belief entirely erroneous We prefer not to criticise Dr Molson's attitude as the principles and practice of bio-chemistry as far as we can understand them do not admit of serious discussion in a medical journal Miss Murdoch was in the circumstances compelled to meet Dr Molson and to allow his method of treatment to be employed for it would have been impossible to ignore the letter from Mr Sharp authorising Dr Molson to take entire charge of the patient

FAMILIAR LINES

To the Editors of THE LANCET

SIRS —In THE LANCET of Feb 14th you are good enough to say that the lines Our Doctors quoted on p 448 from the *Westminster Hospital Gazette* have a familiar ring to us The lines in question are a quotation from my Song of the General Practitioner (see p 29 of Musa Medica a Sheaf of Song and Verse) and I want to thank you for your kind reference I am Sirs yours faithfully

Feb 23rd 1903 J JOHNSTON

OZONE

To the Editors of THE LANCET

SIRS —One of the latest of the cases in my practice in which I have employed this valuable antiseptic and in which I found very decided and very rapid benefits from its administration I consider quite worthy of being recorded A patient aged 17 years was suffering from pneumonia complicated with pleurisy his temperature was 105° F with very rapid and laboured breathing, his lips were cyanotic and in fact all the symptoms were very grave I adopted the usual treatment and the symptoms not improving on the third day I introduced ozone The same evening there was a marked change for the better the pulse had fallen from 110 in the morning to 100 the breathing was less rapid and less laboured and the temperature was 104° The symptoms continued to improve gradually all the bad symptoms subsiding and the patient I am happy to say made a very favourable recovery I at first employed the ozone for a quarter of each hour gradually extending its use until it was used continuously I may mention another case of diffuse cellular erysipelas The presence of ozone produced an important change in the atmosphere of the patient's room whilst there was an obvious benefit to the patient

I am Sirs yours faithfully

THE Y FUND

SURGEON GENERAL H S MUIR begs to acknowledge subscriptions from Colonel T F McGann I M S (retired) and Captain Hefferan R.A M C. also further contributions from the officers of the Indian Medical Service in civil employment kindly collected by the Director General of the Indian Medical Service (Sir B Franklin K C I E) making a total from that source of £313 6*s* 2*d*. The gross amount collected was nearly £918 Of this sum £750 have been invested in the names of trustees (Surgeon General Muir Surgeon General A H. Keogh C B and Lieutenant-Colonel W Babtie V C C M.G) for the benefit of the infant. Of the remainder a portion has been devoted to establishing Y" in a position which gives her congenial employment, and the balance after deducting necessary legal and other expenses (which will not exceed £12) will be handed over to her She is extremely grateful and returns her sincere thanks to all who have come forward with their generous assistance

A Country Practitioner —Every patient has the right to select his or her own medical adviser and to change him at will. But when a practitioner is called upon to supersede his professional brother it is his duty to ascertain that the former medical adviser has been properly informed that his services are no longer required In this case the patient seems to have recurred to the original medical adviser We cannot judge of the conduct of the temporary medical adviser because we do not know in what terms he was invited to attend or what steps he took in reply But surely no harm has been done.

A B C —The Rensum bit is a flexible indiarubber rod passing behind the bit proper which prevents a horse from taking the bit between the molars, which is the usual prelude to bolting It is quite humane Reference has already been made in THE LANCET to the Rensum bridle.

E H A —The practice has obvious advantages but is not suitable in the case of delicate children The family medical man should be consulted before the change in the child's habit is made There is no risk of flatfoot

W A B —1 The answer depends upon the distance of the stream from the source of pollution A chemical analysis might be made of the water 2 and 3 The contingencies alluded to are impossible.

M H H is referred to THE LANCET of Jan 18th, 1902, p 183. The method was simply immersion in a strong solution of silicate of *soda (10 per cent)*

L B is thanked for his communication, but arrangements are made at this office for the regular receipt of such information.

M.B —We regret that we are unable to help our correspondent.

Medical Diary for the ensuing Week.

LECTURE I

Delivered on Feb 9th

Mr. President and Gentlemen,—I almost owe you an ology for bringing to your notice a few points, hardly any which, I fear, are very novel, on the subject of the vermi- rm appendix In spite of the widespread attention which as of recent years been given to this lymphoid appendage ere is still a very considerable difference of opinion on any points connected with its anatomy and physiology, to y nothing of the pathological conditions associated with it so much has our knowledge of the organ and its lesions en increased that it would seem that there is but little left be added to the sum, yet it is perhaps at just such a stage experience that it is well to gather together some of the portant facts in lectures such as these. I shall not allude detail to all the well known statements concerning its oss anatomy but only to some which, however simple and parently obvious, are sometimes lost sight of

Gross Anatomy of the Appendix.

First, let it be remembered that the vermiform appendix is olly an intra peritoneal organ, using this term in the sense which it is generally employed—that is to say, it is always spended by a fold of peritoneum—the meso-appendix—in a nner similar to a loop of intestine, while its extreme tip usually quite free. The obvious deduction from this mentary fact is that the appendix cannot be approached any route whatever which does not transgress the ritoneal cavity—in other words, one in which the parietal yer of peritoneum is always incised.

Dr R J A. Berry[1] has very carefully worked out the rieties of the attachment form, and relations of the meso- pendix Briefly he summarises the differences in the scriptions given by various authors as follows "These are, st, the shape of the meso-appendix, whether triangular or adrilateral, and secondly, its relations to the vermiform pendix, whether a complete or an incomplete investment that organ." From a careful review of the fold in 100 ses he comes to the following conclusions 'The meso- pendix is a double fold of peritoneum which entirely rounds the vermiform appendix, constituting its sentery Though generally of a triangular aspect it is ways quadrilateral in outline—that is to say, four borders n always be described, though one border may be so short to give one the impression that the structure is triangular

In most cases the mesentery can be demonstrated to naked eye extending along the whole length of the pendix, and in those cases where the meso-appendix pears only to extend midway along the appendix croscopic examination will conclusively prove that a ritoneal covering is investing the whole length of the pendix." While from a personal examination of r 50 normal appendices I can fully indorse all that Berry affirms, I think that he partly loses sight of pathological and, therefore, surgical, significance of fact that the breadth of the fold constituting the so-appendix may vary very much Thus undoubtedly in a ge number of cases the meso-appendix as a distinctly quadrilateral fold extends the whole length, or nearly the whole length, of the appendix, but, on the other hand, there is no inconsiderable minority of instances in which it does not reach as such a fold to the termination of the tube. It is because of this shortened attachment of an actual fold that the appendix is so frequently curved or bent upon itself and it is by no means unusual for a division of the meso-appendix to be required in order to straighten out the tube Away then must go all the statements of operating upon the appendix extra peritoneally

A second fact is the direct communication with the cæcum proper This connexion is merely, as it were, a safety valve against explosion and not in the vast majority of cases the entrance through which an irritant foreign body passes into the tube. It is frequently after this communicating aperture has become abnormally closed that trouble ensues rather than when it is unusually patent The calibre of this aperture, while amply sufficient in its natural state to allow the free evacuation of secretion from the mucous membrane of the tube itself, is not great enough to permit the entrance into the lumen of the appendix of bodies of considerably smaller dimensions than those which have been said to have passed through it.

The position of the aperture is interesting and so is also its relation to the axis of the tube. Too little attention has perhaps been paid to the fact that the passage from the cæcum into the appendicular canal is, as it were, hidden away under the loose folds of mucous membrane which surround it, indeed, in some instances it is difficult to determine its position. This is obviously very different from the character of the larger adjacent opening—the ileo cæcal—which guarded rather than obscured by the folds constituting the ileo-cæcal valve, is very apparent, for the ileo-cæcal junction appears prominent as if somewhat telescoped into the cavity of the large intestine, while that of the appendix is depressed and may have to be searched for As a general rule the relative position of these two apertures is that the orifice of the vermiform appendix is some 2 5 to 3 5 centimetres inferior and posterior to the ileo cæcal Then, again, in at least two of the fairly common positions of the appendix—namely when lying upwards and inwards or directly upwards—its orifice is in reality, at any rate, in the upright position, at the most dependent part of the tube, and this facilitates the exit of secretion and hinders the entrance of extraneous material. But it must be here remarked that the foregoing meets with an exception in the case of bacteria which, as it were, creep along the surface of the mucous membrane lining the entrance to the tube, and also of intestinal worms, which occasionally glide over the surface into the tube. It is wonderful how the various pointed foreign bodies found within the lumen of the tube have discovered the narrow aperture, cast around as it is with everything that would seem to block their way

A third subject of extreme interest and importance is the position of the appendix within the abdomen. To guess correctly where the tip of the appendix lies in any given case, without exposing it, is well nigh impossible To state that such and such a position is the *normal* one for the appendix is only to make oneself liable to have the statement completely overthrown by the next observer The cæcum with its vermiform appendage only reaches its common habitat in the right iliac region after a considerable route of migration and this fact is quite sufficient in itself to lead to very different relations of the organ. It is probable that in a small number of instances the cæcum has not fully reached the right iliac region even at birth and may continue its journey for some months after intra uterine life Thus there are on record instances in which the vermiform appendix has been discovered lying close beneath the liver and even behind the right lobe of the same gland (Fig 1)

With regard to what may be conveniently termed the normal positions there are three in which the appendix generally lies —1 Pointing upwards and inwards towards the region of the spleen This may be described as being the north east position 2. Pointing downwards and inwards over the brim of the true pelvis. This may be described as being the south east position. 3 Pointing directly upwards behind the cæcum. This may be described as being the due north position. Various authors state differently as to which of these three is the most usual position Personally, from the observation of nearly 200 cases in the dissecting-room and post-mortem room, I am convinced that a direction upwards and inwards behind the inner part of the cæcum

hen the appendix is first fingered is indicative of a cal condition

face —The surface of the serous covering of the should normally be perfectly smooth and regular e should be no adhesions other than those of a haracter The whole length of the tube should be n circumference except for a slight tapering at the tremity Any sudden bulgings or enlargements disease.

HYSIOLOGY OF THE VERMIFORM APPENDIX.

ally little or nothing is known concerning the y of the tube and it may be that its physiological s are in reality insignificant, though they may have ring upon its pathology There are two conflicting to its primary functions, one that it is entirely an e organ, the other that it is purely an excretive Probably the real truth lies in the statement that art absorptive and in part excretive.

r, it has been thought that it has to do with the n of sulphuretted hydrogen to aid in the antisepsis arge intestine. There can be no doubt that the ymphatic character of the appendix seems to point bsorptive function. The extremely well marked d follicles and the large lymphatic spaces and both tend to make the assumption feasible that ndix is chiefly concerned with absorption. Yet, on r hand, there are some strong arguments against theory Its absorbing surface is practically infini- compared with that of the adjacent small and large . Then, again, what is it to absorb? It is a very nt fact that it is well nigh impossible even under to distend the lumen of the appendix by distending um with fluid, exactly in the same way as it is not be able to fill the lower end of the ileum from the This conclusion is also corroborated by the fact that lom or never the case that the lumen of the vermi rocess is affected in those instances in which the has given way under the strain of distension arising nstriction of the large intestine on the distal side cæcum Further, the lumen of the appendix is receptacle for meconium, so that it would not appear at the appendix often has any liquid contents, other at it has itself secreted, to absorb.

, it is a point of interest that the action of the r fibres forming one of the coats of the tube tends, ey contract, to force its contents towards and into ty of the cæcum. That the mucus is here of assist- lubricating hardened fæces and helping in their passage is past believing, for the contents of the cæcum, although designated ' fæces," are not even id and therefore require no such help I do not that there is evidence to justify the belief that endix produces sulphuretted hydrogen, in fact, the lge that the mucus contained within it is often inodorous is greatly against the theory Until, how ere is an accurate chemical analysis of the secretion possible to be sure as to whether it may not have nction in the economy

LECTURE II

Delivered on Feb 11th

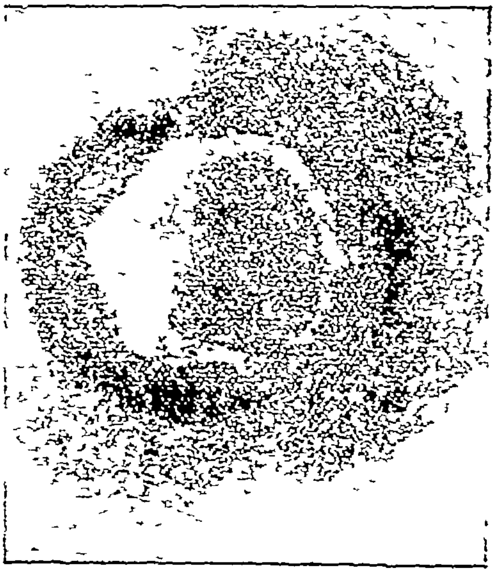
ETIOLOGY OF INFLAMMATION

PRESIDENT AND GENTLEMEN —Can an inflammation appendix sufficient to excite symptoms ever be of a cterial nature? I would venture to answer this ques- cidedly in the negative It is my firm belief that stance of so-called appendicular colic, slight appendi tarrh of the appendix, and a number of other con designated by like somewhat vague terms, is in truth lent upon an actual inflammation of the appendix and ith a bacterial origin.

perfectly willing to admit that in some, perhaps instances in which an appendix is examined after d where symptoms pointing to it have been in ce, bacteria may not be found. But it is to be bered that most of these are excised after the oms have nearly or completely disappeared—in fact, the quiescent stage. It is therefore quite possible nce the inflammation has passed, the bacteria which d it may have vanished On the other hand an ation of the increasing number of appendices removed during an attack, and some of these attacks of only a slightly greater severity than a "mild" preceding one, show not only the presence of bacteria but an abundance of infective micro-organisms. It is open for an objector to say that these organisms are present in every appendix, whether it be the site of inflammation or not, and that the bacteria must therefore play little or no part in the inflammatory process when in progress. Granted that the constant presence of bacteria in greater or fewer numbers is true, this fact only tends to strengthen further the supposition that parasites are the essential cause of the inflammation. They are present, they can incite inflammatory processes, and if some starting cause ensues they will produce the condition of distinct inflammation with symptoms

If it be conceded that all cases of inflammation of the appendix with symptoms are the outcome of bacterial infection, what deductions should be drawn therefrom? First, that it is impossible to say what will be the limits of any given attack, merely a few days' malaise with slight colicky pain referred to the right iliac fossa, or death from septic peritonitis or septicæmia. Secondly, that should the sufferer apparently recover from the attack, there will probably remain, in a now more than ever damaged appendix, bacteria always ready to light up a fresh inflammation on the least provocation. (Fig 3.)

FIG 3



Section of appendix with calculus in situ (× 25)

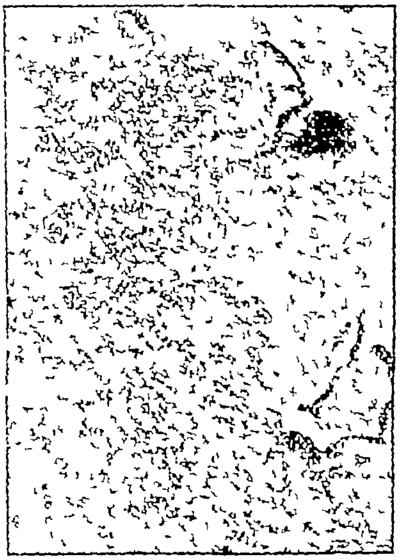
BACTERIOLOGY

Many varieties of bacteria may be found within the lumen of the appendix, in the walls of the tube, in the lymph formed on its serous surface, in the adherent portions of omentum in the peritoneal fluid, in consecutive abscess cavities in distant collections of pus and even in the blood and remote organs They may be classified as follows 1. *Bacilli.*—(*a*) Bacillus coli communis in its various forms, (*b*) bacillus pyocyaneus, (*c*) bacillus prodigiosus, and (*d*) bacillus tuberculosis. 2 *Cocci* —(*a*) Staphylococcus pyogenes aureus, (*b*) staphylococcus pyogenes albus, (*c*) streptococcus pyogenes citreus, and (*d*) diplococcus pneumoniæ. (Fig 4)

As to the frequency with which the more common individual organisms are found the following may be taken as a fairly accurate estimate based, as it is, upon the combined results of the investigations of many authorities (1) varieties of the bacillus coli communis 94 0 per cent., (2) bacillus pyocyaneus, 0 5 per cent, (3) bacillus prodigiosus 0 5 per cent., (4) bacillus tuberculosis 2 0 per cent, (5) staphylococci, 1 5 per cent., and (6) streptococci, 1 5 per cent. The bacillus coli communis is the only organism which is commonly found alone in cases of appendicitis Cocci are but rarely present by themselves, though they are more often found in association with the colon bacillus. (Figs 5 and 6.)

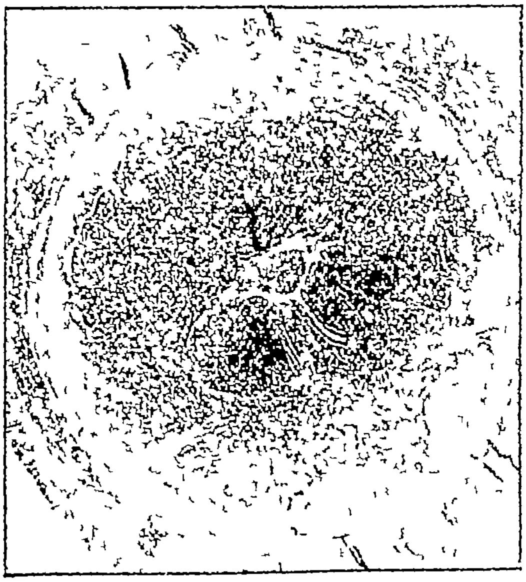
Tuberculosis of the appendix may be primary or merely part of a general infection of the alimentary tract. In its primary form, which is decidedly rare, it is apt to be very chronic, producing signs and symptoms of a chronic appendicitis In these instances the mucosa and the submucosa will ordinarily be the parts involved, the serous membrane frequently remaining free. Now and then there are seen instances in which connective tissue hyperplasia is the predominant anatomical feature of the lesion, giving rise to a mass which to the naked eye is very difficult to distinguish from a new growth. This hyperplasia is probably the outcome of a low virulence of the bacillus and a consequent disinclination to caseation and a great increase of newly formed connective tissue in place of it

Fig 4



Calculus from the same appendix as in Fig 3 showing colon bacilli ($\frac{1}{12}$ oil immersion)

Fig 5



Section of inflamed appendix showing great infiltration of the mucosa and pus in the lumen (× 25)

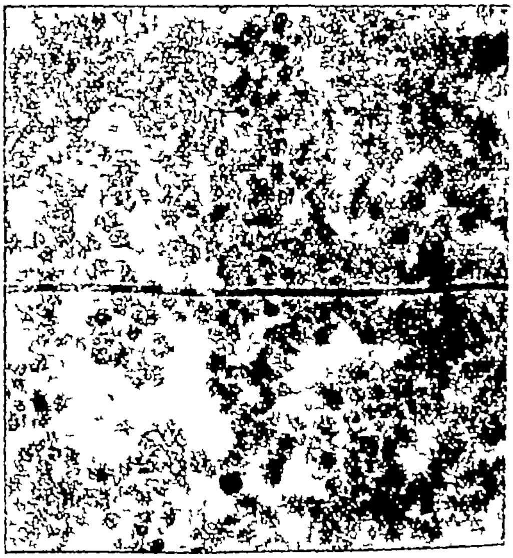
Secondary tuberculosis of the appendix is by no means rare and as a rule presents no marked signs or symptoms of its own presence, these being masked by those of the more extensive infection.

Calculi and Concretions.

It may be stated at the outset that these are always formed *in situ* within the lumen of the appendix Although it is possible that their nucleus may have found its way from t cæcum into the appendix, yet the bulk of the material the calculus has been laid down within the tube it Concretions or calculi may occur in almost any part of alimentary tract and they may produce no signs symptoms or they may give rise to most serious in the way of irritation, inflammation, ulceration, perforation, or obstruction The calculi of the appendix may behave precisely the same manner as calculi elsewhere in with the intestines The malignity of calculi, and particularl of appendicular calculi, would seem to depend on one of conditions, first the presence of virulent micro org within or upon them, and secondly their movement. If were possible to have a stationary and non septic calculus little harm would result, but as soon as such a concretion infected with organisms or changes its position, it is liable produce dire consequences.

The surface of the calculi is usually fairly smooth and th are frequently rounded or elongated in form,

Fig 6



Pus from the lumen of the same inflamed appendix as in Fig 5 showing colonies of staphylococci ($\frac{1}{12}$ oil immersion)

presenting facets These three facts would seem to me indicate that the calculi have been subjected to a amount of movement, perhaps caused by ineffectual eff on the part of the appendix to rid itself of its contents. But, on the other hand, a calculus may markedly tuberculated on the surface This latter is associated with a crystalline deposit and is observed in those calculi which are stationary and which found within a distinct cavity in the appendix

An interesting point in connexion with the formation appendicular calculi is the question as to whether they arise without the walls of the tube being separated them by a distinct space There can be no doubt, I from the observation of fresh specimens, that is before process of hardening has been employed, that the walls closely embrace the calculus and that the actual ment of the lumen of the tube has occurred in cons of the growing calculus within it, rather than that increase in size existed prior to the formation of concretion.

Actinomycosis of the Appendix.

The actinomyces may attack any portion of the tract, or the fungus may infect the adjacent distant parts through dissemination from the That actinomycosis may be a primary lesion of the is now an established fact, though the condition is sarily a rare one

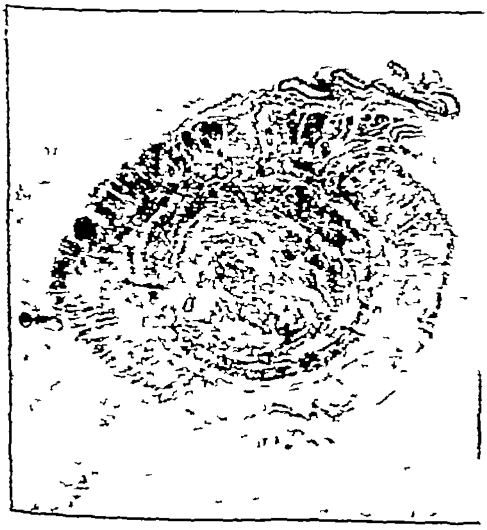
A recently recorded case[2] illustrates the condition as it is usually seen. The patient had for some time been employed as a stable-boy in a hotel and had previously been a farm labourer He had been the subject of hydrarthrosis of the right knee-joint at the age of 15 years but had made a rapid and complete recovery under treatment. He had lost three or four molar teeth during the past three years. He had long been in the habit of chewing blades of grass, grains of wheat, &c., when not quite ripe. His symptoms began with acute pain in the right iliac fossa, with recurring rigors, frequent nausea, and progressive malaise and debility On several occasions there was a rise of temperature. The symptoms at first improved under treatment by rest, careful diet, and inguinal compresses moistened with tincture of opium. This improvement was succeeded by lassitude, persistent anorexia, and slight constipation, together with some loss of flesh. On palpation there was no tenderness in the region of the appendix but a small tumour above Poupart's ligament on the right side, it was about from three to four fingers breadth in the vertical direction and was very hard to the touch The appendix was removed and on microscopical examination typical actinomycosis was revealed

One important point in the prognosis of actinomycotic inflammation of the appendix is the fact that there is a great liability for the wounds made, either to drain an abscess or even to remove a non suppurating appendix, to have a marked tendency to become the seat of secondary infection with the fungus. It is therefore well to bear in mind the possibility of this infection in those instances in which a series of sinuses form after a lesion occurring primarily in the region of the right iliac fossa. In one case under my care these sinuses tracked upwards in the sheath of the rectus abdominis muscle almost to the thorax and downwards behind Poupart's ligament into the thigh and outwards into the lumbar region

EFFECTS OF INFLAMMATION

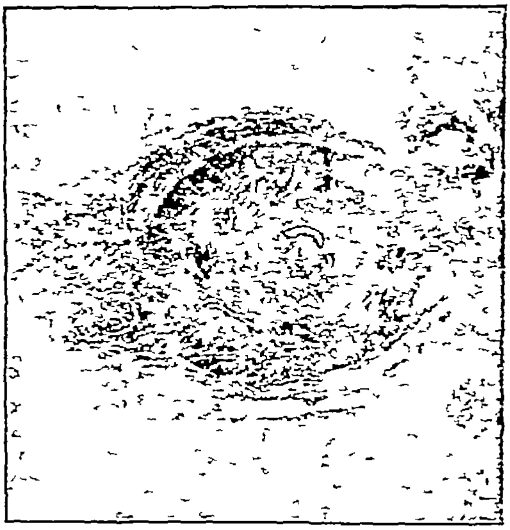
One effect of inflammation is obliteration of the lumen of the appendix. This is entirely an opposite condition to that of perforation. It is in this manner that nature may bring about what is sometimes termed a "spontaneous cure." There is also a natural tendency for the appendix to become obliterated in its lumen as age advances and it is for this reason that acute inflammations of the tube are less common in later life. In order however to bring about complete immunity to a recurrent appendicitis it is necessary that the whole of the lumen of the tube should be obliterated. (Fig 7) This result is not so very usual, for from attacks of inflammation there may be obliteration only of a small part of the tube If this is at the distal portion it leaves the proximal part still in communication with the cæcum and still liable to the invasion of bacteria. If it is at the proximal end it shuts the rest of the lumen off from that of the cæcum and opens the door for the formation of a cyst of the appendix. If bacteria are shut up in the portion of the lumen which lies on the distal side of the obliteration an empyema may result But take those instances in which, on a series of sections being cut from many parts of the length of the organ and all showing complete obliteration of its lumen it is somewhat difficult to explain the undoubted attacks of pain, and of severe pain, that some of the possessors of such an altered tube have suffered from. (Fig 8) A possible explanation exists, however, in the fact that the majority of these appendices are found when exposed to be very closely bound down by adhesions to the surrounding parts and it may be that tension on these peritoneal bands induced by peristalsis or movements of the psoas muscle gives rise to the pain and discomfort. Whatever may be the actual explanation the fact remains that a removal of the altered appendix relieves the sufferer of all his troubles

FIG 7



Section of sclerosed appendix proximal end, lumen obliterated (× 25)

FIG 8



Section of the same appendix as in Fig 7 distal end, a trace of lumen remains (× 25)

The histological appearances of these appendices in which the lumen has become completely obliterated varies considerably in different instances. In most the elements of the lympho-mucosa are to all intents destroyed and their place is taken by a mass of cicatricial tissue In some sections here and there may be seen remnants of the glands or of the lymphoid follicles. In many the muscular layers seem to be a good deal hypertrophied

SECONDARY ABSCESSES.

I only draw attention to these because I wish to emphasise the possibility of their occurrence at quite late periods after the complete removal of the appendix I have myself had one case in which no less than five years after the removal of the appendix in the usual manner a secondary abscess formed close to the cæcum at the site of the stump of the appendix. These collections may be due to several causes. One is that a few bacteria are left behind which remaining latent may at a remote period light up a fresh suppuration. Another is that a silk ligature or suture has remained and has been the source of the irritation. A third is that a small portion of gauze has been accidentally left behind in a case in which drainage was required in spite of the removal of the appendix. All these causes are quite apart from those instances in which secondary suppuration occurs as the result of an incomplete operation in which too long a stump of the appendix is left or in which a peri appendicular abscess has been drained and no attempt has been made to excise the appendix. Cullen[3] has recently described an interesting case in which a retrocæcal abscess developed three years after the complete removal of the appendix and has well illustrated the condition.

EXAMINATION OF THE BLOOD IN APPENDICITIS

Recently a considerable amount of attention has been given to the examination of the blood as an aid in the diagnosis of appendicitis While admitting that the hæmatological examination and significance may be carried too far, yet there can be no doubt of its usefulness as a help in diagnosis when employed with due consideration of other signs and symptoms There are two distinct changes in the blood associated with appendicitis, both of which are very obvious and both have a recognised bearing upon treatment and prognosis. These two alterations are (1) anæmia and (2) leucocytosis.

1 *Anæmia* —One has been often struck with the intensely anæmic appearance of some patients who have been suffering from toxæmia for many days. Not only is this anæmia apparent in the face of the person, but it is very evident when the blood is minutely examined In several instances in which poisoning was due to absorption from the products of an infective appendicitis I have found a very marked diminution both in the actual number of erythrocytes and the percentage of hæmoglobin The suddenness with which these changes may occur is a necessary factor in the importance with which they are to be viewed There are, of course, conditions causing rapid loss of blood, as ruptured ectopic gestation, which must be carefully excluded. If the lessening of the erythrocytes is very great the proportionate loss in the percentage of hæmoglobin is tremendous, for while the average decrease in the oxygen carriers in instances of appendicitis of any form is about 15 per cent, according to the most recent statistics, that of the corresponding loss of hæmoglobin is no less than 25 per cent. Supposing, then, the fall in the hæmoglobin is between 35 and 50 per cent., whether or no the red corpuscles are correspondingly diminished in number, the question of operative interference becomes an anxious one for the surgeon In some instances of the repeated attacks of the so-called catarrhal appendicitis there is a certain degree of anæmia, especially in young women and in those where there is chronic constipation. When the blood is examined there is a diminution in the red cells and hæmoglobin but without leucocytosis I consider that in these cases probably both the anæmia and the appendicitis are dependent upon a disordered state of the alimentary tract and if the condition does not rapidly improve under careful dieting and good hygienic surroundings I am convinced that the removal of the appendix is indicated, as the continued anæmia may really be due to slight toxæmia by absorption from the appendix It is remarkable how rapid is the return to health in certain of the cases after the removal of the source of poisoning is carried out. I would venture to suggest that more attention be paid to the anæmia arising in cases of chronic appendicitis or at least in those of chronic digestive trouble with suspicion of distinct local lesions of the appendix.

2. *Leucocytosis* —Of recent years the question of leucocytosis in association with appendicitis has been engaging a considerable amount of attention, and although there are very divergent views as to the degree of importance that can be placed upon the condition yet taken in conjunction with other signs and symptoms the determination of its presence may be of the greatest assistance (1) in the diagnosis of suppuration before operation, (2) in the diagnosis of secondary suppuration after operation for abscess, and (3) in the differential diagnosis of appendicitis from other affections It is often a matter of extreme difficulty to say in any given case of inflammation of the appendix whether or not a focus of suppuration has formed It is equally true that in the vast majority of instances in which pus is being produced in the tissues there is an increase in the number and an alteration in the characteristics of the white corpuscles circulating in the blood It would seem therefore that given a case of appendicitis in which leucocytosis is obvious the surgeon may safely assume that suppuration is in evidence or that the case is one that demands operative interference.

I will cite two examples as types in which a blood count taken in conjunction with a general view of the case distinctly assisted in the diagnosis, and therefore in the treatment, of the lesion Both are taken from Cabot's excellent review of the subject[4] The first case (Case 40, Cabot) is one in which the blood count showed a progressively increasing leucocytosis which in the end decided the for surgical interference. The age of the patient, a m was 19 years, and the blood count showed 4,380,000 *red* The *white cells* were as follows on March 25th, at 9 P M 15,600, with vomiting, pain, and tenderness, on the 2 19,500, the patient being comfortable with no vomiting the signs more localised, on the 28th 22,900, there slight tenderness only, on the 29th 35,300, the bowels mov ing well, with no symptoms, and on the 30th 32,800, w operation was performed, a large amount of pus being f This is a typical case and one in which the other sig and symptoms present did not point to the formation of and the necessity for surgical interference. The second (Case 20, Cabot) is one of exactly opposite nature T patient in this case also was a male who had suffered appendicitis for 24 hours with a resistant abdomen Oct. 23rd the white cells were 20,100, on the 24th at 9 14,000, at 4 P M 12 000 and at 10 P M 13 250 (no tion), and on the 25th at 8 A M 8750 (the patient liquids every two hours) and at 3 P M 9600 although there was a distinct leucocytosis on the first day the affection yet the signs and symptoms were but slig and on the next day there was a rapid fall in the number leucocytes which seemed to indicate—and that correctly, the progress of the case proved—that there was no sup tive process in evidence. The number of leucocytes drop to nearly normal on the third day of the attack.

As has been recently shown by Dr C J N Longrid there is a tendency in those cases in which the in inflammation of the appendix is so severe as to cause gangrene of the tissues forming its walls for a very mar leucocytosis to be present Thus, in his published tabl 36 cases, in no less than six instances there was a l cytosis of from 20 000 to over 30 000 and in all the appen was found on exposure to be gangrenous but not surro with pus. I have observed the same in two cases in on operation the appendix was found gangrenous with hours of the onset of the symptoms and in both of there was a considerable amount of non purulent sli irritating fluid in the peritoneal cavity Both pat spite of washing out of the abdomen, intravenous injection &c., succumbed to an intense toxæmia. One was that of a strong and active young man, aged 20 the other that of a young married woman, aged 27 who was robust and healthy

As to the causation of this condition there is dispute Purulent and gangrenous processes both high count of white cells as a rule, that of purulent ditions being fairly easy of explanation, but gangrenous more difficult Virulence of the toxin resisting power of the individual have much to do degree of leucocytosis. Generally speaking, the intense the poison and the greater the resistance, the will be the leucocyte count

In both cases mentioned above the subjects were y apparently in the enjoyment of good health, sing active, and robust The onset of the infective p sudden and the poisoning intense, but their resistanc great Hence there was a rapid and surprisingly augmentation of leucocytes, the count in both 35,000 within 48 hours of the first indication of the I think that it is a fact that most of these cases of so- "fulminating" appendicitis occur in young active, persons who are therefore just those who conform conditions of marked inflammatory leucocyto intense infection and great resistance

Unfortunately, in a fair proportion of the cases in inflammation of the appendix has reached the stage of puration and the case can only be treated by drainage is a great liability for secondary abscesses to form the region of the primary mischief or at distant parts. in such cases that a blood count may again be of Another case taken from Cabot's series (Case 18) illus this very clearly In this case, on Nov 5th, the whi were 21,700 (first operation), on the 10th, 21,400, 13th, 16 000, on the 15th 24,400, on the 16th, 20, the 19th, when the second operation was performed pus pocket was found 47,700, on the 20th 16 700, 21st, 13,000, on the 22nd, 10,700, on the 26th when a operation was performed, a pus pocket being again f 30,200, on the 27th, 20 000, and on the 28th, 17, Dec. 4th, 11,900, and on the 26th, 11,300

The Hunterian Lectures

ON

THE NATURE AND ANATOMY OF ENTEROPTOSIS (GLÉNARD'S DISEASE)

Delivered before the Royal College of Surgeons of England on March 2nd, 4th, and 6th, 1903

By ARTHUR KEITH, M D ABERD, F R C S ENG,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND ETC

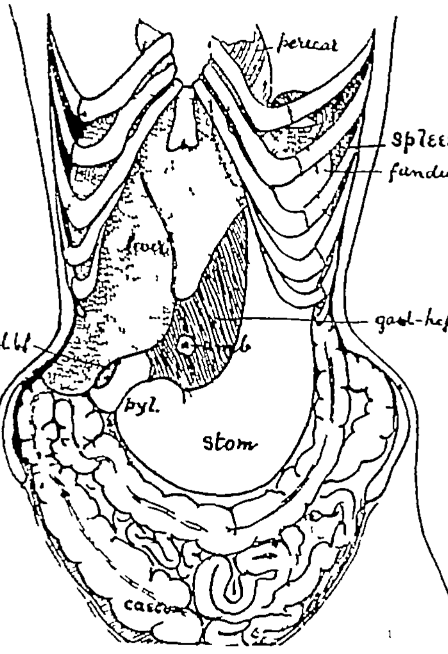
LECTURE III[1]

Delivered on March 6th

PTOSIS OF THE LIVER AND STOMACH

MR. PRESIDENT AND GENTLEMEN,—Displacement of the liver and stomach springs chiefly from two causes—either from the relaxation or paresis of the abdominal muscles which maintain the visceral shelves on which these organs are supported or, as is more frequently the case, the body cavity is constricted by clothing or contorted by disease, so that the normal respiration swing forwards cannot take place In either case the visceral displacements are much the same.

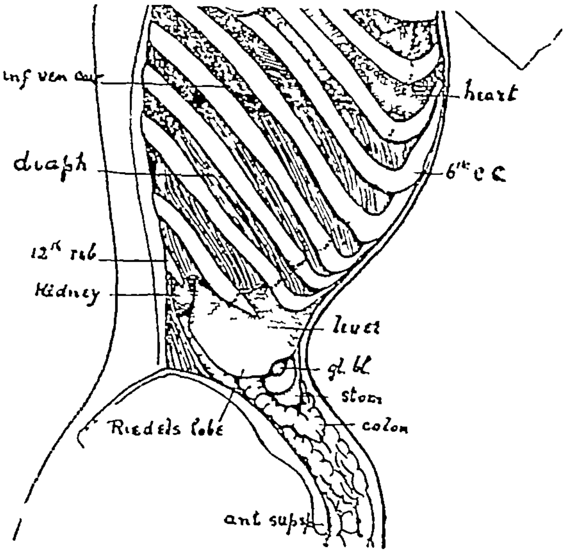
FIG 14



A case of partial ptosis of the viscera in a woman aged 45 years. The waist, which measured 26 inches in circumference was reduced to 22 inches by corsets The viscera were then hardened *in situ* by the injection of formalin The duodenum descended as far as the brim of the pelvis

The position and shape of the liver and stomach shown in Figs. 14 and 15 are characteristic of the general type of enteroptosis so frequently met with in our dissecting room. The subject from which the illustrations shown in Figs. 14 and 15 were made was a woman, aged 45 years in whom the viscera were fixed and hardened *in situ* by the use of formalin after her natural waist of 26 inches had been reduced to 22 inches by corsets a reduction quite within the limits of ordinary practice The condition of the viscera shown was present before death, the corsets merely help to emphasise the natural characters of the displacements. To understand how such a condition has been produced a number of points have to be observed. The extrusion of the viscera from the subdiaphragmatic space is due (1) to the constriction of the thorax, (2) to the pressure applied to the epigastric region which prevents the stomach and liver swinging forwards so as to over ride each other, and (3) to the depression of the ribs (see Fig 15) which throws the costal fibres of the diaphragm into a more vertical position, they tend then to press the viscera downwards rather than forwards The corsets when worn prevent an inspiratory depression of the liver, the viscera become, when so restrained by the application of corsets, a fulcrum on which the chest is raised But when the corsets are removed or undone the muscles of the wall of the abdomen, being weak from disuse, are ill equipped to oppose the action of the diaphragm. In the body shown the subcostal arch is narrow, but had the patient lived it would have opened out as the viscera were displaced further downwards until, instead of measuring 50°, it would have reached 90° or more.

FIG 15



Lateral view of the same subject as is shown in Fig 14

Riedel's lobe —Why is it that in partial or complete cases of visceral ptosis there is always a tendency for the lower extremity of the right lobe of the liver to be produced into a linguiform process (Riedel's lobe), such as is shown in Figs 14 and 15? Two circumstances have to be taken into account. 1. The part of the right lobe which lies beneath the tips of the tenth and eleventh ribs is the first to escape from beneath the lower margin of the thorax, the pressure of the costal margin tends to separate the part extruded from the part within the thorax. 2. But a more important circumstance lies in the fact that the space between the crest of the ilium and the tips of the eleventh and twelfth ribs is the part of the abdominal wall least protected by muscular support. Fasciculi of the external and internal oblique are the sole muscle supports in this region Owing to the crest of the ilium, from which they act, projecting further outwards than the tips of the eleventh and twelfth ribs, on which they act, these muscular slips tend to draw the ribs outwards rather than inwards during expiration and hence are ill designed to prevent the displacement of the liver towards the right loin. This is markedly true of the female (see Fig 14)

FIXATION OF THE KIDNEYS.

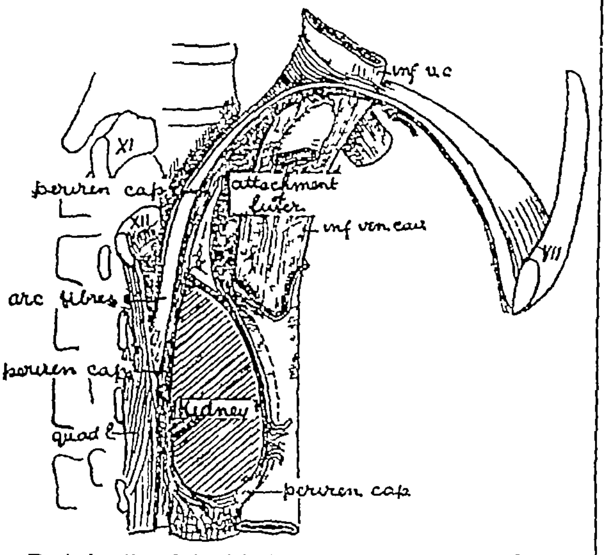
If one will analyse and estimate the various forces which maintain the kidneys in their normal position, it will be found that by far the most important is the constant pressure exerted on them by the diaphragm on the one hand and the muscles of the abdominal wall on the other Unlike the liver, the stomach, and the spleen, the kidneys rest on no visceral shelf While the diaphragm exerts its force directly on them the muscles of the abdominal wall can act only indirectly through the abdominal viscera. In front of the right kidney are the liver duodenum, colon, and small intestine, in front of the left kidney, the stomach, spleen, colon, and small intestine, through these the muscular wall of the abdomen maintains the kidney against the diaphragm, quadratus lumborum and psoas muscles.

---

[1] Lectures I and II were published in THE LANCET of March 7th 1903, p 631.

Next in importance to the muscles is the loose connective tissue or perirenal capsule in which the kidney is imbedded. Recently the capsule has been differentiated by Zuckerkandl into two layers—the pre nephric and post nephric fasciæ, but every time I seek to demonstrate the described disposition and relationship of these fasciæ I feel that I make a greater demand on the imagination of my students than on their powers of observation Moreover Zuckerkandl's description of the perirenal capsule makes a simple matter difficult. As a passive renal bond the perirenal capsule is of the very first importance. By it the kidneys are bound to the diaphragm and for practical purposes to the diaphragm only At the upper pole of the right kidney the tissue of the capsule fuses with the connective tissue of the mesepaticon on the right side (Fig 16) and with the tissue of the coronary ligament of the stomach and suspensory ligament of the spleen on the left side Along with the viscera just named the kidneys are fixed to the arcuate fibres of the diaphragm (Fig 17) At the outer border of each kidney the capsule is continuous with the dense subperitoneal fascia of the diaphragm and transversalis fascia and muscle, but at the lower pole of the kidney the tissue of the capsule is loose and open and freely permits the respiratory descent of the kidney The meshes of the posterior layer of the capsule become laden with a peculiar fat from one to two months before birth. The fat serves as a perirenal bursa or slide on which the respiratory movements of the kidney take place.

FIG 16

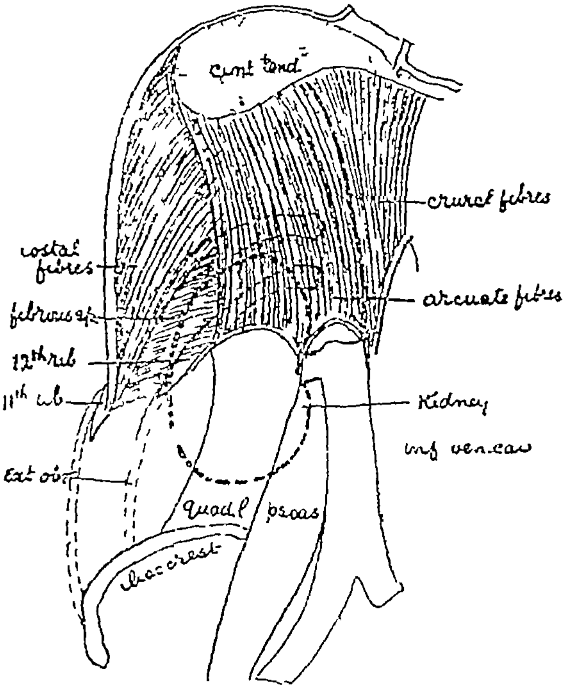


Vertical section of the right kidney in situ to show its relationship to the diaphragm and perirenal capsule. The position shown is that of complete inspiration The diaphragm was thrown into a condition of contraction by the application of boiling water

There is too, another renal bond also connected with the perirenal capsule—namely the renal pedicle. The pedicle is made up (1) of the renal artery, (2) of the renal vein, (3) of dense connective tissue derived from the radix mesenterica which fuses with the perirenal capsule at the inner border and hilum of the kidney and with the fibrous covering of the suprarenal bodies, and (4) of the renal plexus of nerves and lymphatics The renal pedicle limits the extent and direction of the movements and displacements of the kidney As a bond the peritoneum which covers the anterior or outer surface of the kidneys may be left out of account, it is so designed as to permit renal respiratory movements, it is so attached that it could only prevent a displacement in an upward direction. It is attached loosely over the lower ends of the kidneys so that these organs may descend easily on the quadratus lumborum and psoas

Respiratory movements of the kidney.—Since the inspiratory descent of the kidney is entirely produced by the contraction of the diaphragm the extent and direction of the movement are best understood by observing the relationship of the kidney to the fibres of that muscle (see Figs. 16 and 17) It is convenient to divide the kidney into two parts—viz., the *supracostal*, or diaphragmatic, the part above the twelfth rib or its representative, and the *infracostal*, or lumbar part, resting on the psoas, quadratus, and transversalis tendon (Fig 17) The kidney is in relationship only with the arcuate fibres which, arising from the arcuate ligaments, expand somewhat outwards as they ascend behind it. The supracostal part of the kidney also rests on the fibrous interval between the arcuate and costal fibres, which in 40 per cent of bodies is relatively as great as is shown in Fig 17 The fibrous space marks the former communication between the pleural and peritoneal cavities, the muscular fibres which bound it mark the outer edge of the primitive digastric band like diaphragm Above the kidney the liver is bound to the arcuate fibres on the right side (see Fig 16) and to the spleen and stomach on the left These structures, being pulled downwards by the arcuate fibres in each breath taken, push the kidneys downwards and inwards before them, the extent of the excursion varying from two to four centimetres with each breath. The kidneys, and the viscera attached in the hypochondrium above them, are pulled down on the arcuate fibres as logs on a sledge In this movement the *loose perirenal capsule and fat in front of the* quadratus lumborum and psoas act as a renal slide The renal pedicle controls to some extent the direction of the movement. On expiration the muscles of the abdominal wall, especially the transversalis, return the kidney to the initial inspiratory phase

FIG 17

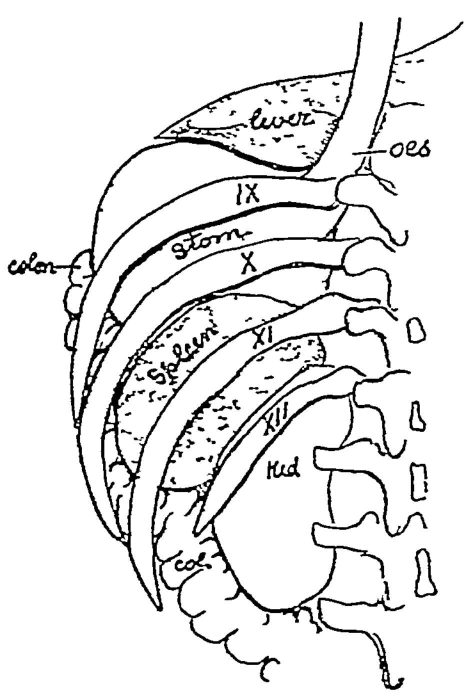


Showing the relationships of the right kidney to the diaphragm

Displacements of the kidney.—The condition essential to the displacement of the kidney, whether right or left, is a diminution of the subdiaphragmatic space. Unfortunately such a diminution may be produced in many ways (1) by compression of the thorax with clothing, (2) by a partial collapse of the thoracic walls following chest or spine disease, and (3) by the permanent contraction of the diaphragm which follows a relaxed or paretic condition of the abdominal walls. In cases of general enteroptosis the muscular fasciculi of the diaphragm measure on an average only two and a half inches, against three and a half to four inches in a condition of health I suspect, too, that in some cases of pleurisy the diaphragmatic connective tissue is contracted or in a cirrhotic condition which leads to a diminution of the diaphragmatic domes When the sub-diaphragmatic space is reduced, then the part or parts most easily ejected are displaced below the costal margin.

Displacement of the left kidney—Why is it that the left kidney is so seldom displaced? The answer is that the left hypochondrium is provided with a safety valve in the shape of the splenic flexure of the colon, which is so formed and fixed that it may enter or leave the hypochondrium with the greatest freedom as the stomach empties or fills. The mechanism will be better understood by referring to Fig 18, which represents the position of the organs in the left hypochondrium from behind when the stomach is full. When full the liver, as Symington and Cunningham have pointed out, is tilted more into the right hypochondrium, the left kidney is forced half an inch or more downwards, the spleen is carried outwards on the distended fundus of the stomach, but the part which is displaced by far the most is the splenic flexure of the colon. Professor Birmingham has clearly described the manner in which the colon replaces the gastric contents. Hence it is that when the left hypochondrial space is reduced, the splenic flexure, being in the habit of going and coming can accommodate itself to a partial or complete subcostal position, leaving the kidney and other organs undisturbed. The extrusion of the colon, however may not be enough to compensate for the diminution of the hypochondrium, then the stomach, the spleen and the kidney are all displaced. On the right side there is no obliging moveable viscus, the liver and kidney fill the diaphragmatic dome and either the one or the other must make way or as more commonly happens a part of both is extruded when the subcostal space is reduced in size. Hence the frequent presence of a Riedel's lobe of the liver with a partial displacement of the right kidney There are, however several other circumstances which give the left kidney a more secure position than the right. 1. The left kidney is bound to the spleen and the spleen is bound by its suspensory ligament to the diaphragm. 2. The arcuate fibres draw down the unwieldy heavy base of the liver on the right kidney, the fundus of the stomach, drawn down on the left kidney represents a lighter hammer

FIG 18.



The position of the splenic flexure the spleen and the left kidney when the stomach is full. When empty the kidney and spleen ascend an intercostal space while the splenic flexure is moved upwards into the angle between the spleen and stomach

Displacement of the kidney in women—It is commonly said that the kidney is ten times displaced on the right side for once on the left and that renal displacements are ten times more common in women than in men. Yet at birth the two kidneys are equally placed, through a long series of human fœtuses I noted no difference of sex, of size or of individual in the position of the kidneys In fact the only variable factor then is the relationship of the cæcum to the right kidney, it is commonly bound in front of the hilum, but it may lie internal to the kidney or in the loin below it On the other hand, the splenic flexure of the colon is always bound to the front and outer border of the left kidney

The liability of women to renal displacements begins at puberty and increases in frequency with each decade up to the fifth As the female sexual characters are developed the iliac crests expand outwards and the transverse intercristal diameter of the body becomes greater than the transverse diameter of the lower part of the thorax by an inch or more. In children, as in primates, the pelvis is narrower than the chest. In some women, from natural conformation or from an exaggeration of the natural form by the use of stays, the iliac crests may project outwards on each side two inches or more beyond the lateral wall of the thorax formed by the lower ribs. The eleventh and twelfth are the only ribs that have a relationship to the kidney (see Fig 17) As far as their movements are concerned both of these ribs may be regarded as part of the abdominal wall. They ride outwards and inwards with the inspiratory expansion and expiratory contraction of the abdominal wall. The muscles which depress them and thus limit the space in the loin into which the kidneys descend during inspiration are fasciculi of the external and internal oblique which rise from the crest of the ilium. When the projection of the iliac crests and the depression of the lower ribs become marked these muscular fasciculi, instead of compressing the loins and assisting the expiratory return of the kidney tend rather to prevent its return by expanding the capacity of the loins In this sexual character is to be found at least one of the causes which render women more liable to kidney displacements than men.

High versus low waists.—It frequently happens that in women who bear evidence of constriction from corsets the right kidney is situated at a higher level than usual, occasionally it may be found completely above the twelfth rib In such cases a long lumbar region has allowed the waist to be formed well below the costal margin, the constriction of the corsets forces the kidney upwards, in short waists on the other hand, the waist is formed at or above the level of the kidney In connexion with the formation of the waist the relative size of the twelfth rib must be taken into account The twelfth rib is more frequently short or vestigial in the female than in the male.

Relationship of the colon to the kidney—Cases have been recorded by Sir Frederick Treves and Dr T J MacLagan and similar cases have been described and discussed by Mr J Hutchinson, jun.,[2] in which a floating right kidney has given rise to obstruction of the bile-ducts In such cases ptosis of the liver and stomach with great elongation of the gastro-hepatic omentum will be found, much like the conditions shown in Fig 14 Besides these derangements three others may be noted when the viscera are exposed by the reflection of the belly wall. 1. The head of the pancreas and duodenum are displaced forwards as well as downwards being almost completely extruded from below the liver 2. The hepatic flexure still attached to the peritoneum over the kidney is displaced downwards in the right loin 3. The lower pole of the right kidney covered by its peritoneum and partially rotated on the renal stalk, protrudes in an interval on the anterior surface of the abdominal viscera, between the liver above, the hepatic flexure below and the duodenum and pancreas to the left. The kidney causes obstruction of the duodenum rather than of the bile ducts In accounting for this condition the relationship of the colon to the kidneys must be taken into account. The transverse colon is so suspended and folded that it may easily accommodate itself to the respiratory movements of the structures in the hypochondria, to the filling and emptying of the stomach, and to its own state of distension. Its mesentery forms a shelf for the liver stomach, and spleen and is pushed downwards if these organs are displaced At each end the transverse colon is fixed closely to the peritoneum over the kidneys by the hepatic and splenic flexures but the part at the hepatic flexure lying just below the liver is less

---

[2] The Practitioner February 1902.

adapted for movement than the part below the stomach near the splenic flexure If then there is ptosis of the subdiaphragmatic viscera, or if the colon be overloaded and distended, the peritoneum over the kidneys is drawn downwards and forwards owing to the traction exercised on it by the displaced transverse colon The hepatic segment being the more fixed cannot be depressed without pulling on the peritoneum over the right kidney, thus making a space into which the kidney may be displaced forwards. It is the forward displacement that constitutes a *floating* kidney

FIXATION OF THE INTESTINAL TRACT

Up to this point attention has been directed to the fixation and movements of the human viscera, but now, in seeking to unravel the complicated and peculiar manner in which his intestinal tract is fixed, it is necessary to turn to the scheme of visceral fixation in other animals

Seventeen years ago, from this same chair, Sir Frederick Treves solved many problems regarding the arrangement of the human peritoneum by a reference to the rich field of mammalian anatomy It is most profitable, however, to turn at once to the primates, that order of mammals with which man has been brigaded from ancient times and from the stock of which, if there is aught of truth in the process of evolution, man certainly sprang Point for point, even in minute detail, the abdominal and thoracic viscera of the great anthropoids—the orang, gorilla, and chimpanzee—are fixed in the same manner and situations as in man (Fig 19)

FIG 19

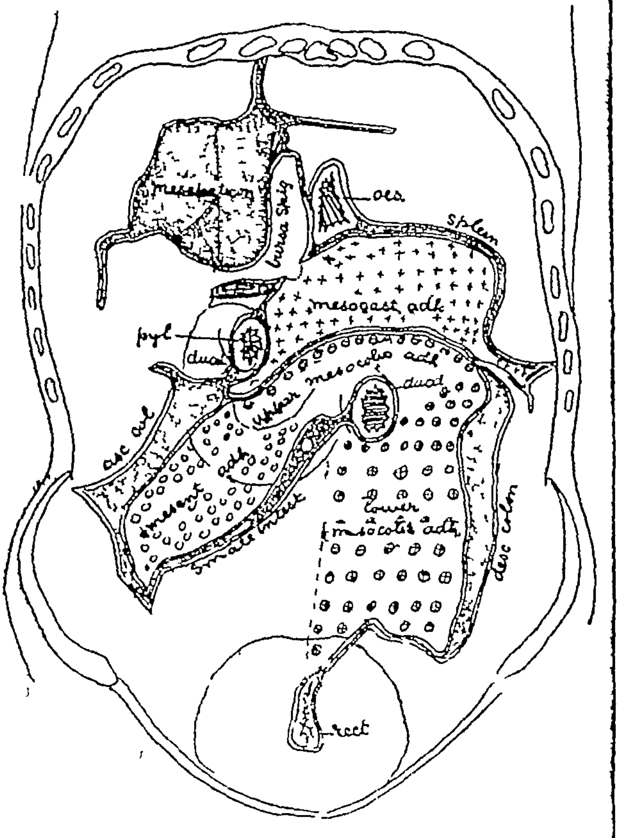


Diagram of the posterior wall of the adult human abdomen showing the areas of visceral fixation Four of the five areas of mesenteric adhesion are represented by distinctive marks: + mesogastric adhesion O mesenteric adhesion Θ upper mesocolic adhesion ⊕ lower mesocolic adhesion

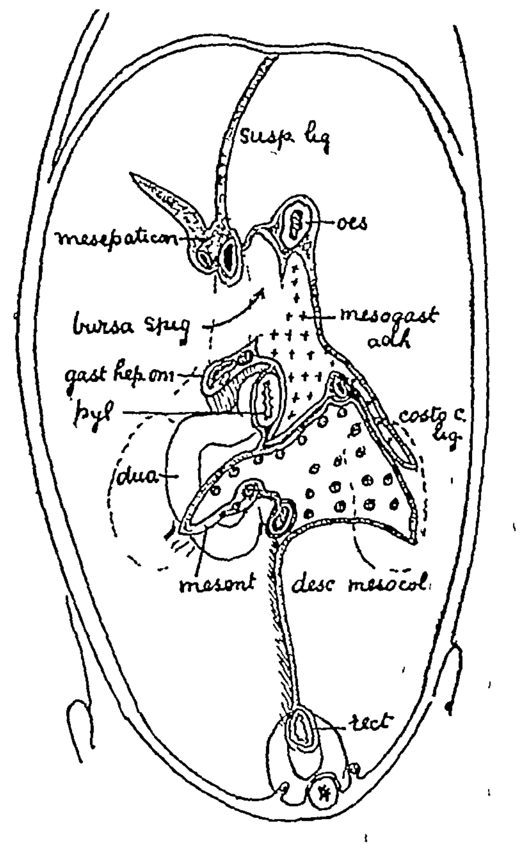
To find a condition parallel to that in the commoner forms of apes or pronograde monkeys one must take the arrangements of the peritoneum found in the child at birth or a little after birth (Fig 20) The manner in which the viscera are fixed in the lowest primates, such as some South American monkeys or in lemurs generally, is morphologically identical with the human condition at the third month of development (see Fig 21) The net result which one brings back from a study of the anatomy of the primates is, that with the evolution of the orthograde posture and orthograde type of respiration, mesenteric adhesions, which appeared one after the other in five different areas, spread out and bound the alimentary tract more and more to the abdominal wall, as the animal became more orthograde in posture. The manner in which the viscera are fixed in man results from his posture and respiration The cells which bring about these mesenteric adhesions fill the broad base of the fœtal mesentery, but how they became sensitive to the new needs of the evolving organism is a problem yet to be solved. The five areas of adhesion referred to above (see Figs 19, 20, and 21) are the following (1) mesogastric, (2) mesoduodenal, (3) mesenteric, (4) upper mesocolic, and (5) lower mesocolic

The mesogastric adhesion (Fig 19)—Although the dorsal mesogastrium is produced into the great omentum in all primates, it is only in man and orthograde primates that its root becomes adherent to the posterior abdominal wall. The cœliac axis marks its original point of attachment, from there the process of adhesion spreads outwards over the left suprarenal body and upper part of the left kidney until it reaches the spleen which is attached to the mesogastrium. In 85 per cent. of children at birth the process of adhesion has extended almost to the outer border of the left kidney, thus binding the spleen to that organ. Since the tail of the pancreas lies in the root of the mesogastrium it also becomes adherent to the posterior wall of the abdomen

The mesoduodenal adhesion.—The adhesion of the right aspect of the mesoduodenum to the hilum of the right kidney is, with the exception of the mesenteric, the latest to appear It is commonly incomplete, the adhesion mainly affecting that part of the duodenum across which the colon passes. The *duodenal adhesion can* always be easily undone and by so doing the freest surgical access is obtained to the lower or post-duodenal stage of the common bile-duct. The adhesion extends after birth outwards on the kidney

FIG 20

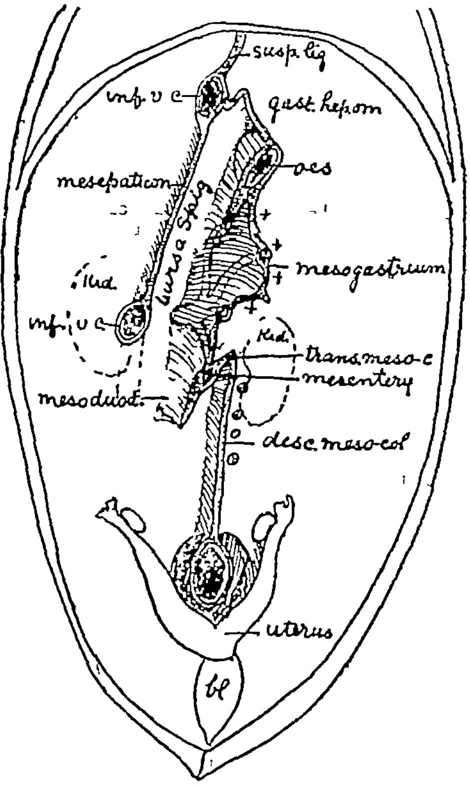


The visceral attacnments and mesenteric adhesions of a pronograde ape (*Semnopithecus cinereus*) The markings indicating the mesenteric adhesions are the same as those used in Fig 19

The lower mesocolic adhesion (see Figs 19, 20, and 21) — The process of adhesion, which leads to the fixation of the splenic flexure to the front of the left kidney and of the descending colon and its mesentery to the left loin, is earlier in appearance than either the mesoduodenal or mesenteric, but later than the mesogastric and upper mesocolic. It is seen only in the orthograde group of primates and is an adaptation to the upright posture The mesentery of the splenic flexure and descending colon is primarily attached in the middle dorsal line along the aorta, being continuous anteriorly with the radix mesenterica and mesentery of the duodenum The process of adhesion, commencing in the base of the mesentery, spreads outwards by a species of growth over the left kidney and left loin until the colon itself adheres to the parietal wall. The process of adhesion proceeds to a variable extent in the mesosigmoid It may proceed down into the iliac fossa and fix closely the upper part of the omega loop there or it may stop short and give rise to the inter sigmoid fossa.

The upper mesocolic adhesion —By this adhesion the transverse colon, the hepatic flexure, and the ascending colon are fixed in position, the cæcum and appendix being developed as protrusions from the bowel have no proper mesenteries This, the primary adhesion of the five is present in all primates and is the most difficult to describe. The important circumstance to remember is that the duodenum and upper segment or cæcal region of the colon are developed at the same time and side by side from the base of the yelk sac, their mesenteries forming one continuous mass Dr Chalmers Mitchell has shown that in birds and mammals alike these two structures—the duodenum and cæcal segment of the colon—are united by a fold of mesentery The duodenum and colon being thus adherent the mesogastrium when it grows out meets with the mesocolon. It is 20 years since Lockwood discovered that when the mesogastrium and mesocolon came in contact the process that leads to their fusion or union starts at their bases and spreads forwards to their visceral attachments. The process of fusion proceeds furthest in man and the anthropoids Further, the great omentum formed by a ballooning of the mesogastrium envelops the whole of the upper segment of the colon. In the human child at birth the cæcum varies widely in position, in seven infants out of ten it was adherent in front of the right kidney or duodenum, in three it lay in the loin and iliac fossa below the kidney The ascending colon and ascending mesocolon are formed as the child learns to walk by an extension downwards into the right iliac fossa of the primary adhesion to the kidney

FIG 21



The visceral attachments in a low primate (*Lemur coronatus*)

Respiratory movements of the transverse colon.—While the hepatic and splenic flexures of the colon are closely adherent to the right and left kidney and accompany them in their respiratory movements, the transverse colon is swung loosely by its horizontal mesocolon and accommodates itself to the free respiratory oscillations of the organs in the subcostal region The transverse mesocolon forms a shelf for the subdiaphragmatic viscera and separates them from the coils of the small intestine. The transverse colon is markedly displaced in cases of enteroptosis, the descent of the subdiaphragmatic viscera carries it and its mesocolon downwards Mr Arbuthnot Lane has called attention to the traction and obstruction exercised on the hepatic flexure in displacement of the transverse colon. The same observation applies to the splenic flexure and seeing how intimately the colon flexures are adherent to the kidneys the displaced colon may also exercise traction on them

The mesenteric adhesion —The adhesion of the mesentery of the small intestine to the posterior wall of the abdomen, in an oblique line drawn from the termination of the duodenum to the cæcum, is a character of those primates which are adapted to the orthograde posture (Fig 19) The mesentery of the small intestine together with that of the ascending and transverse colons, is originally a fan shaped sheet with only its apex attached at the radix mesenterica There it is wedged in between, and continuous with, the mesenteries of the lower colic segment and duodenum. In the human child at birth only the apex and the colic edge of this fan shaped sheet are attached (Fig 20) That attachment forms the root of the transverse mesocolon, but the rest of the mesentery is free. Immediately after birth the process of adhesion, starting at the transverse or mesocolic edge, spreads downwards in the direction of the right iliac fossa. It is not uncommon for this process of adhesion to be arrested at various stages The attachment may fail and the whole of the small bowel be suspended from the radix mesenterica or the ascending colon, and the termination of the ileum may be left free and these parts are then liable to become the seat of volvulus Even when the mesenteric adhesion spreads to its normal extent the radix mesenterica and superior mesenteric arteries are the main intestinal support

Movements and displacements of the small intestine —The small intestines lie in a special peritoneal compartment formed by the mesocolon and great omentum. Under the pressure of the belly walls they support the horizontal subdiaphragmatic shelf formed by the transverse meso-colon This septum cuts off the respiratory movements of the liver, spleen and stomach. Intestinal displacement may be due either to a diminution of the costal part of the body cavity, the subcostal viscera being thus thrust down on the small intestines, or, on the other hand, the support afforded them by the muscular walls of the abdomen may give way Their displacement is then followed by the descent of the subcostal viscera When the intestines are forced into the pelvis, displacing the pelvic viscera, the traction exercised on the superior mesenteric artery and radix mesenterica causes a partial obstruction of the third stage of the duodenum.

Time and space prevent my dealing with the various displacements that overtake the pelvic organs and pelvic wall in cases of enteroptosis On some future occasion I hope to be able to deal with them.

SMALL-POX HOSPITAL FOR GLOUCESTER.—The Local Government Board has sanctioned the application of the Gloucester corporation to borrow £2000 for the purpose of erecting a small pox hospital

BRISTOL MEDICAL MISSION.—The annual meeting of the subscribers to this charity was held on March 3rd under the presidency of Sir Herbert Ashman. The medical report stated that 8750 patients had been treated during 1902 The financial statement was satisfactory One of the speakers stated that nearly one third of the people of Bristol attended the medical charities of the city which he considered was rather hard on the medical profession.

adapted for movement than the part below the stomach near the splenic flexure If then there is ptosis of the subdiaphragmatic viscera, or if the colon be overloaded and distended, the peritoneum over the kidneys is drawn downwards and forwards owing to the traction exercised on it by the displaced transverse colon The hepatic segment being the more fixed cannot be depressed without pulling on the peritoneum over the right kidney, thus making a space into which the kidney may be displaced forwards. It is the forward displacement that constitutes a *floating* kidney

FIXATION OF THE INTESTINAL TRACT

Up to this point attention has been directed to the fixation and movements of the human viscera, but now, in seeking to unravel the complicated and peculiar manner in which his intestinal tract is fixed, it is necessary to turn to the scheme of visceral fixation in other animals

Seventeen years ago, from this same chair, Sir Frederick Treves solved many problems regarding the arrangement of the human peritoneum by a reference to the rich field of mammalian anatomy It is most profitable, however, to turn at once to the primates, that order of mammals with which man has been brigaded from ancient times and from the stock of which, if there is aught of truth in the process of evolution, man certainly sprang Point for point, even in minute detail, the abdominal and thoracic viscera of the great anthropoids—the orang, gorilla, and chimpanzee—are fixed in the same manner and situations as in man (Fig 19)

FIG 19

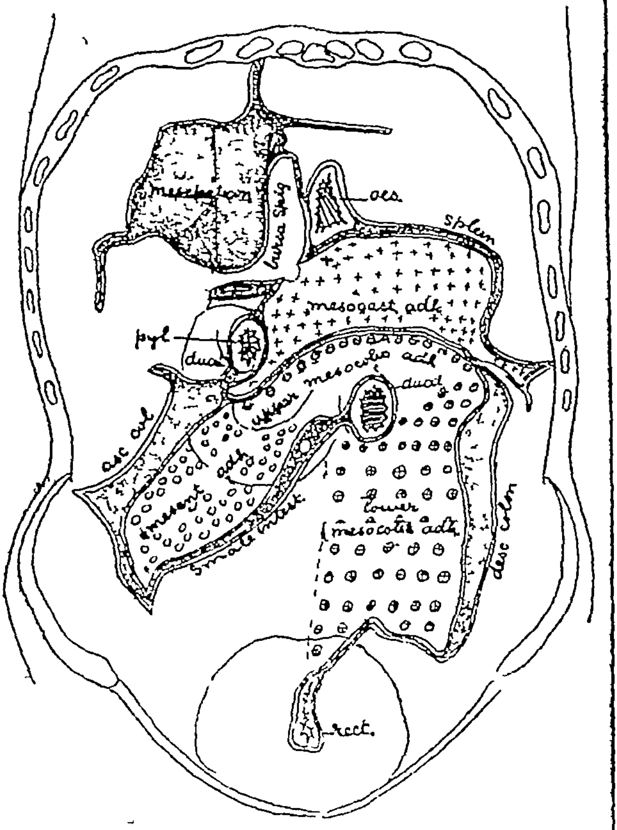


Diagram of the posterior wall of the adult human abdomen showing the areas of visceral fixation Four of the five areas of mesenteric adhesion are represented by distinctive marks: + mesogastric adhesion ○ mesenteric adhesion ϴ upper mesocolic adhesion ⊕ lower mesocolic adhesion.

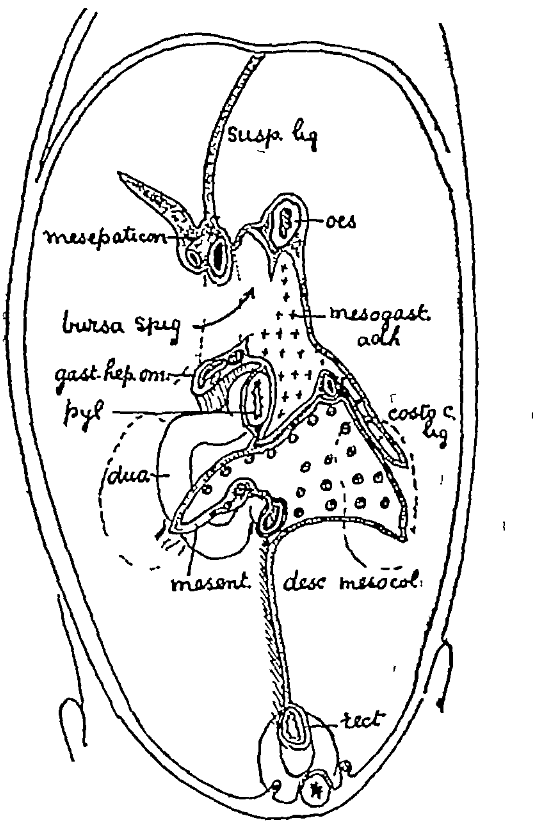
To find a condition parallel to that in the commoner forms of apes or pronograde monkeys one must take the arrangements of the peritoneum found in the child at birth or a little after birth (Fig 20) The manner in which the viscera are fixed in the lowest primates, such as some South American monkeys or in lemurs generally, is morphologically identical with the human condition at the third month of development (see Fig 21) The net result which one brings back from a study of the anatomy of the primates is, that with the evolution of the orthograde posture and orthograde type of respiration, mesenteric adhesions, which appeared one after the other in five different areas, spread out and bound the alimentary tract more and more to the abdominal wall, as the animal became more orthograde in posture. The manner in which the viscera are fixed in man results from his posture and respiration The cells which bring about these mesenteric adhesions fill the broad base of the fœtal mesentery, but how they became sensitive to the new needs of the evolving organism is a problem yet to be solved. The five areas of adhesion referred to above (see Figs 19, 20, and 21) are the following (1) mesogastric, (2) mesoduodenal, (3) mesenteric, (4) upper mesocolic, and (5) lower mesocolic

The mesogastric adhesion (Fig 19) —Although the dorsal mesogastrium is produced into the great omentum in all primates, it is only in man and orthograde primates that its root becomes adherent to the posterior abdominal wall. The cœliac axis marks its original point of attachment, from there the process of adhesion spreads outwards over the left suprarenal body and upper part of the left kidney until it reaches the spleen which is attached to the mesogastrium. In 85 per cent. of children at birth the process of adhesion has extended almost to the outer border of the left kidney, thus binding the spleen to that organ. Since the tail of the pancreas lies in the root of the mesogastrium it also becomes adherent to the posterior wall of the abdomen.

The mesoduodenal adhesion.—The adhesion of the right aspect of the mesoduodenum to the hilum of the right kidney is, with the exception of the mesenteric, the latest to appear It is commonly incomplete, the adhesion mainly affecting that part of the duodenum across which the colon passes. The duodenal adhesion can always be easily undone and by so doing the freest surgical access is obtained to the lower or post-duodenal stage of the common bile-duct. The adhesion extends after birth outwards on the kidney

FIG 20



The visceral attachments and mesenteric adhesions of a pronograde ape (*Semnopithecus cinereus*) The markings indicating the mesenteric adhesions are the same as those used in Fig 19 form may remain perfectly well for many years Three months ago I saw a man, aged 62 years, whose urine had a specific gravity of 1036, it contained much sugar, gave no ferric chloride reaction, and he appeared perfectly well. He said that sugar was detected in 1885 and that he had dieted carefully for the last ten years Such a case as this casts doubt on the view that hyperglycæmia is harmful. It is true that many a patient with this form of glycosuria has a little albuminuria and rigid arteries, that he is liable to gangrene or boils, and that he bears operations and illnesses badly, but are not all these, like the glycosuria, to be regarded as evidence of structural and functional decay rather than as due to the glycosuria? However, it must be remembered that the passage of sugar being a loss of energy is in itself harmful, but as the amount of sugar is usually small this loss of energy is generally unimportant. It is strongly in support of the above view that this form of glycosuria is met with chiefly in elderly people. There is sometimes a tendency to treat these alimentary cases too severely It is not necessary to reduce the carbohydrates in the food beyond the point that leads to their disappearance from the urine But the urine should be more carefully examined than is usually the case, for an alimentary lævulosuria[9] has been described. A complete record of such a case, giving the effects of the administration of dextrose and lævulose, would be very valuable and we should like information as to the value of Seliwanoff's test for lævulose.[10] To be strictly accurate we ought to speak of alimentary dextrosuria and alimentary lævulosuria as the case may be. It will be noticed that I have assumed (what I believe to be true) that while many patients with so-called alimentary glycosuria are really in the early stages of composite diabetes, yet others are examples of a much less harmful condition which always remains alimentary glycosuria, never passes on to composite diabetes, and lacks the serious metabolic phenomena of this disease Whether this is so is a very fair subject for discussion.

The occurrence of sugar in the urine due to diseases or injuries of the nervous system is of little clinical interest. It is usually slight and transitory If the nervous lesion causes coma and sugar is found in the urine the case may at first be mistaken for diabetic coma. I was called to a case not long ago in which this mistake had been made, but the failure to find either acetone or aceto-acetic acid in the urine showed the case to be one of nervous glycosuria The patient died from cerebral hæmorrhage and it was found that blood had passed down the iter in the fourth ventricle. Dr A. P Beddard has kindly directed my attention to a similar case[11] in which acetone chanced to be in the urine. Aceto-acetic acid was not looked for but doubtless ferric chloride would have shown its absence. Testing for the ferric chloride reaction will always prevent a mistake between a nervous lesion causing coma with sugar in the urine and diabetic coma.

We now pass on to consider diabetes proper or, as Dr Pavy calls it, "composite diabetes" This may be defined as a disease in which dextrose is present in the blood and urine and in which, if the disease is untreated, ultimately lævo-rotary β hydroxybutyric acid appears in the blood and urine and the output of carbohydrates in the urine is greater than can be accounted for by those in the food. By far the most important sugar in the urine is dextrose but small quantities of lævulose, pentose combined glycuronic acid and other closely allied bodies are sometimes present. We know that there is a great excess of sugar in the blood and that this excess is very largely due, and probably in many cases—at any rate in the early stages—entirely due, to the failure of the body to utilise the sugar, but even in many severe cases the power to utilise sugar is not entirely lost But this is not in all cases the entire explanation of the presence of sugar in the blood for in a severe case of diabetes there may be sugar in the blood and urine even if carbohydrates are entirely absent from the food. Such sugar must come either from proteids or fat and the prevailing opinion is that it comes from the proteids, for, in the first place diabetics do very well on fat and in the next place only a little sugar could be produced even from a large amount of fat.[12] But it is clear that even in a case in which some carbohydrate is present in the food we cannot tell whether some in the blood may not have been derived from the tissues if the patient has not completely lost his power of utilising ingested sugar

The next point of interest is not nearly sufficiently grasped—namely, that many diabetics can utilise lævulose much better than dextrose. Many observers have noted this and I have frequently observed it It is said[13] that a diabetic patient soon loses his power to utilise lævulose, but I know that he may retain it for a long while and by examining the urine we can soon see when he is losing his power. This ability to utilise lævulose suggests that experiments might be made to see whether diabetics can utilise other sugars—e.g, pentose.

I have read many articles on diabetes which contain no reference to the extraordinary fact that, as was pointed out by Dr Pavy many years ago and which I have often observed, a diabetic patient who is on strictly carbohydrate-free diet may, if a little carbohydrate is given, excrete far more sugar than that given This is so important and so little known that I may be excused for quoting word for word from Dr Pavy[14] "The information supplied goes to show that not only may starch and sugar ingested traverse the system unappropriated but that their ingestion may act in such a way upon the complaint as to give rise to the elimination of more sugar than could be derived from the principles themselves Thus after sugar had for some days been entirely absent from the urine under restriction to an animal regimen two ounces of ordinary bread per diem were for a couple of days allowed and then the restricted diet again resumed. During the first day that the bread was taken the patient passed 117 grains of sugar and during the second 196 grains The following day he passed 213 grains, the next 571 then 236 grains, and lastly 92 grains After this there was an absence of sugar By the four ounces of bread the elimination of 1425 grains of sugar was occasioned which is more than could be derived from the bread itself, for I found the whole of the solid matter in the bread consumed only amounted to 1200 grains, against the 1425 grains of sugar discharged in the urine Another point worthy of attention is that the elimination of sugar continued increasing for two days after the bread had been discontinued." Thus we see that the administration of sugar may act as a direct excitant of sugar formation in the body (presumably from proteid) and if in any case some of the sugar taken is utilised we have no means of knowing whether or not some of that in the urine is not derived from the tissues which have been excited to form sugar by the ingestion of carbohydrates No explanation of the carbohydrate metabolism in diabetes will be satisfactory unless this fact is remembered.

Then, again, we want an explanation of the strange disappearance of sugar when coma comes on. This may be of great practical importance. Not long ago I saw with Mr E F White of Putney a patient who was not known to have diabetes she became comatose in the course of influenza and the first specimen of urine examined contained no sugar, but we were put on the right path by finding an abundance of aceto-acetic acid Many years ago I tried giving one or two patients syrup but it had no effect on the coma and they did not live long enough for us to determine whether there was an increased output of sugar

We much need information as to why the body fails to utilise dextrose It has not lost the general power to oxidise—it can use fats, lactates in a diabetic are oxidised to carbonates and benzol is oxidised to phenol. The only explanation which is open to us appears to be that usually offered—namely, that before the sugar can be oxidised it has to be prepared in some way and the diabetic lacks the power to do this Many symptoms —e g polyuria, the high specific gravity of the urine and pruritus vulvæ—can obviously be explained by the presence of sugar, but, as previously mentioned, I think many symptoms are ascribed to hyperglycæmia on insufficient evidence, for instance, we are told[15] that the e ' results of hyperglycæmia consist chiefly in a striking tendency to

ON THE PROBLEM OF GLYCOSURIA AND DIABETES[1]

BY W HALE WHITE, M.D, F R C P LOND,
PHYSICIAN TO AND LECTURER ON MEDICINE AT GUY'S HOSPITAL

WHEN I accepted the honour of an invitation to speak at this debate I never dreamed it would fall to my lot to open it. Had I done so I should not have dared to accept, for the subject is so vast and the difficulties are so great.

The first thing that naturally attracts our attention is the recognition of dextrose in the urine. The universally employed copper reduction test is unsatisfactory As an example I may mention that about 20 years ago, when the nervous theory for diabetes was in the ascendant, it was urged in support of it that the urine of lunatics frequently contained sugar Dr G H. Savage and I[2] showed that this was not so, the mistake probably arose from confounding the reduction given by kreatin and the other reducing bodies in the urine with that given by sugar We all know the difficulty in life insurance work of estimating the value of a dirty greenish brown precipitate given by boiling urine with copper solution and an alkali. We have probably all come across people condemned as diabetic who are not and the mistake has arisen either from the use of a stale copper solution or because of an abundance of reducing bodies in the urine which are not sugar Those who are alkaptonuric are usually condemned as diabetic. The polarimeter, fermentation, and the formation of osazone crystals are all excellent tests, but the first requires an expert, the second is tedious, and the third needs time, there may be delay in the formation of the crystals and glycuronic acid also gives crystals which, however, are in rosettes of thick plump needles, not bundles of long needles like those of phenyl glucosazone We want someone to get up and to tell us that he has found a test by which small quantities of dextrose can be detected in the urine as easily as small amounts of albumin. We also want to know more about the appearance of glycuronic acid[3] in the urine. Do some people pass it and later become glycosuric? One case I have seen suggests but does not prove that this may be so A woman whom I saw ten years ago complained of thirst and dry skin, the urine had a low specific gravity (1008), contained no albumin, but gave on many occasions an abundant brick red precipitate on boiling with Fehling's solution It did not ferment. I saw her again a few weeks ago and she is now passing genuine sugar, but the urine does not give a ferric chloride reaction Bearing on this we have Futcher's[4] paper in which he shows that both fusel oil and tertiary amyl alcohol cause both dextrose and glycuronic acid to appear in the urine. Then, too, it appears that some sufferers from diabetes pass a little glycuronic acid and it has even been stated that minute amounts of this acid may be found in healthy urine Indeed, it must be remembered that there is every reason to believe that its appearance depends upon its being provided with something to combine with rather than on any disturbance of carbohydrate metabolism. Have any here present practical experience of Bial's[5] test for it? There is, I think, no doubt that in most cases the presence of glycuronic acid is asserted on insufficient grounds A copper reducing body is found which is not sugar and it is assumed to be glycuronic acid

Allied to this is another subject on which we want further information—namely, that we occasionally see patients suffering from exophthalmic goitre who for a long while pass an abundance of sugar in the urine For example, I saw a patient ten years ago with marked exophthalmic goitre and glycosuria. Her medical attendant writes now to say that the glycosuria persisted for two years, slowly the symptoms of exophthalmic goitre have disappeared, and now she is "practically well." Some authors have maintained that glycosuria is particularly easily induced in patients with exophthalmic goitre, but von Schrötter[6] gave such a patient grape sugar in doses of 200 grammes without any appearing in the urine I have notes of one patient with exophthalmic goitre whose father had diabetes and of another who has two sisters who have diabetes. Probably the fact that polyuria, thirst, and great hunger are frequent symptoms met with in exophthalmic goitre is unconnected with the glycosuria, for they occur independently of it and in support of this is the fact that Dr H French,[7] making observations on a patient of mine with severe traumatic diabetes insipidus, was unable to produce glycosuria even by giving large amounts of sugar

We want information about the occurrence of other sugars than dextrose in the urine Clinically, three appear to be important—lævulose, lactose, and pentose Lævulose I will refer to presently Can any speakers give us definite information about the after history of women who during suckling pass lactose in their urine? It is stated that of those who develop glycosuria during pregnancy recovery takes place in three-quarters, with a tendency for the glycosuria to recur in other pregnancies, but we want to know of the quarter who do not recover—do they become genuine diabetics or continue to pass lactose? Also, we want to know if a quarter is not too high a proportion of those who do not recover, probably it is Very few, if any, observations have been made in England on pentosuria Pentose appears to exist in the urine in two conditions—namely, in association with other sugars in diabetes—as, for example, d'Amato has recently recorded the case of a patient with a pancreatic calculus and diabetes in whom the urine contained both dextrose and pentose—and in very rare cases as an independent condition in which although pentose appears in the urine the patient can utilise pentose. Brat[8] has recently recorded a case of pentosuria in a woman, aged 62 years, whose brother also had pentosuria. Some of the patients with pentosuria were morphomaniacs Is pentosuria found in any large proportion of morphia takers? In passing I should like to suggest that as accuracy of language leads to accuracy of thought we should when we know the sugar in the urine to be dextrose speak of dextrosuria, thus harmonising with lævulosuria, pentosuria, and lactosuria.

Talking of nomenclature leads me to ask for a more accurate use of the word diabetes. Even the use of the additional word mellitus does not help, for many speak of alimentary glycosuria as diabetes mellitus As it is now, if I hear a patient has diabetes I do not know whether he has the comparatively harmless alimentary glycosuria or the dangerous disease diabetes in which he is liable to coma and passes oxybutyric acid and its derivatives in his urine. Fagge was of opinion that the word diabetes should be used only for the severer disease and this would be best, however, I doubt whether now this is possible, but at any rate we might adopt Dr F W Pavy's excellent suggestion and speak of alimentary diabetes and use the phrase "composite diabetes" to indicate the patients who pass sugar and oxybutyric acid and its derivatives, of which aceto acetic acid is recognised by the ferric chloride reaction and acetone by the nitro-prusside of sodium reaction, but the detection of acetone is not nearly so important as the detection of aceto acetic acid, for acetone is often present in persons who have no diabetes It cannot be too strongly urged that no case of sugar in the urine has been even superficially examined unless the ferric chloride test has been employed.

We badly want a series of cases recorded with a view of finding out what proportion of these alimentary cases become composite cases. Some will certainly appear to do so, *for many an apparent* alimentary case is really the early stage of a composite case indeed, Ebstein believes that this is so of all alimentary cases Dr Pavy, too is strongly of opinion that alimentary cases *often* at least later become composite unless properly treated Properly treated, however, a patient suffering from the alimentary cases[23] globules stained with osmic acid were present, but even then there was a quantity of granular matter, and a case I have been recently studying and which I hope soon to publish seems to show that the blood may be of quite a pale strawberry and-cream colour and yet contain no fat staining with osmic acid but a quantity of granules which appear to be proteid precipitated by the presence of an ester of cholesterin with one of the fatty acids. The altered colour of the blood may be easily visible in the retinal arteries and it may slowly pass away as the patient improves

Turning to the morbid anatomy of composite diabetes we know that the brain, spinal cord and nerves show no naked-eye or histological changes sufficiently often for such to be regarded as the cause of diabetes. I have frequently examined these and the sympathetic ganglia with negative results[24] But speaking of the nervous system reminds us that the explanation of the fact that the knee jerk is absent in 50 per cent. of diabetics is difficult considering how rare other symptoms of neuritis are There are often striking changes in the pancreas During 14 years at Guy s Hospital out of 6702 necropsies the pancreas was diseased to the naked eye in 142[25] and in 19 of these the diseased pancreas was associated with diabetes. An examination of all the fatal cases of diabetes showed that in a quarter naked eye disease of the pancreas was present. In 16 out of the 19 the gland was much atrophied, shrunken, and indurated, and this is, I think, the typical pancreas of diabetes, of the remaining three in one the gland was atrophied as a result of a pancreatic calculus and in one it was large and indurated Hansemann analysing the figures at the Berlin Pathological Institute found in ten years disease of the pancreas with diabetes 40 times and of these cases in 36 the gland was atrophied. There appears no doubt that destruction of the islands of Langerhans is of great importance in connexion with diabetes. A collection of cases by Steele[26] which has been recently published shows this Of course it is well known that diseases which only partially destroy the pancreas do not cause diabetes. Three points on which we want information in this debate are—(1) is alteration in the islands of Langerhans the essential feature of the pancreatic disease which causes diabetes? (2) can we during life tell which cases have and which have not pancreatic disease? and (3) what is the relationship of the internal pancreatic secretion to diabetes?

Passing to the subject of treatment I need not urge the advantages of withholding carbohydrates from the food for by doing so the patient gains strength and weight, and the excretion of sugar and oxybutyric acid diminishes at any rate in most cases but sometimes I have obtained an intense ferric chloride reaction even after weeks of strict diet and even when the sugar has disappeared from the urine. It often seems to me that in many cases dieting has been too strict and as a rule there is at any rate no harm in milk. In any case I would suggest that when diet will not completely control the glycosuria the patient should be allowed just so much carbohydrate as will not increase the sugar in the urine and when diet will control it he should be allowed carbohydrate food up to just below the point at which it leads to glycosuria Lævulose is certainly the best carbohydrate, it may be given up to any quantity so long as it does not cause or increase the glycosuria. Inulin which is the starch corresponding to lævulose, may also be given, it occurs in dahlia tubers and these may be cooked and eaten like potatoes. There is a pernicious belief among some patients that toast may be taken instead of bread. I need hardly say that this is not so. Although there are many reasons against alcohol yet in a severe case advantage may be taken of its energy-yielding power provided it is unsweetened Many cases are probably not allowed enough fat We should all be agreed that too sudden a deprivation of carbohydrates may lead to coma, but why this is we do not know, nor do we understand the undoubted and very important fact that coma is often brought on by exertion worry or mental anxiety Unfortunately we are much in the dark as to the treatment of coma As is shown by cases recorded by Fagge the injection of normal saline solution will sometimes bring the patient out of coma, but he relapses again in a few minutes. Better still is the use of large quantities of alkali If a patient feels a little drowsy it is a good thing to order 100 grains of bicarbonate *of sodium or 50 of the carbonate dissolved in a pint of milk* and for him to drink three or four such pints in the 24 hours. If the coma is deeper a solution of sodium bicarbonate may be injected subcutaneously, so that at least 200 grains are given at the first injection, or I have given it per rectum, but that is much less certain If the case is at all severe, with an abundant ferric chloride reaction but no coma I am accustomed to order some 50 to 100 grains of bicarbonate of sodium to be dissolved in milk and taken during the day From cases I have watched I am certain that this treatment is useful, and I think that it sometimes tides over a time till the good effect of dietetic treatment is felt. It often fails to save life, but then we must remember that it does not stop the formation of the poison. *It is evidence in support of this* view that diabetics often appear to derive much benefit from alkaline waters The bowels of these patients should be kept well open, for by that means we may eliminate some of the poison, possibly the abdominal pain and vomiting which so often herald coma should be interpreted as an attempt to rid the body of the poison by way of the gastro-intestinal tract. There appears to be no doubt that both morphia and codeine can diminish the excretion of sugar, it will be of interest to hear why they are used less than they were. Aspirin is said to act beneficially in some cases, and I hope we may have some evidence for or against it. Dr A. E. Garrod told me of a child, aged seven years who on fixed diet was excreting 30 grammes of sugar a day, she was put on *15 grains of aspirin a day and the excretion of sugar fell,* varying from six to ten grammes After a week the aspirin was stopped and the excretion of sugar fell to two or three grammes a day It must be remembered that aspirin, being a salicylate, will itself give a ferric chloride reaction. I have tried feeding diabetics on pancreas[27] and have injected liquor pancreaticus subcutaneously but without success, nor does the use of Professor Starling s secretin appear to be beneficial. The treatment of the many associated conditions is beyond the scope of these remarks, but I cannot resist asking whether the number of cases of diabetic phthisis has not diminished of late years. I think that it will be found that it has

The last point to which I would direct attention is whether we are not under the word "diabetes" *really describing* more than one disease, for example are some cases due to disease of the pancreas and some not? are those that have so-called fatty blood different from those that have not? are those in which glycogen is present in the liver different from those in which it is absent? In conclusion, I need hardly say I am well aware that in these few remarks many points of great interest have not been touched upon, but as the subject is so extensive I have confined myself to indicating, although very imperfectly, those which appear in the present state of our knowledge to be the more important

THE USE OF SALICYLIC ACID AS A PRESERVATIVE IN FOOD[1]

By C J MACALISTER, M.D Edin, M.R.C P Lond,
PHYSICIAN TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL, ETC

AND

T R. BRADSHAW, B.A. M.D Dub., M.R C P Lond,
PHYSICIAN TO THE ROYAL INFIRMARY LECTURER ON CLINICAL MEDICINE IN UNIVERSITY COLLEGE LIVERPOOL, ETC

In the course of the past two years our opinions have been sought with reference to the harmfulness or otherwise of the ingestion of small amounts of salicylic acid for prolonged periods and we have consequently been interested in making a careful investigation as to the effects produced by this substance, especially upon the nutrition and upon the digestive processes of the economy, for it is mainly upon these that injurious effects are said to have been exerted. We have been the more interested in our endeavours to gain information upon this matter because it has been evident to us that some industries have suffered considerably by the exclusion of salicylic acid as a preservative from their infection and necrosis of the tissues" This may or may not be so, but considering the many ways in which metabolism in diabetes is perverted it appears rash to ascribe these results to the sugar It is almost impossible to resist the temptation of believing that the wasting is due to the loss of energy in the urinary sugar Many diabetics lose 500 calories of energy a day in their urine and it is said that they attempt to make up for this by utilising their proteids and fats and hence they waste But as Bunge points out, this is a teleological argument and I think most of us feel that teleological arguments are dangerous It would be a valuable observation to record the weight and nitrogenous excretion of a diabetic kept on a weighed ordinary diet but absolutely at rest in bed and therefore not requiring the energy lost in the urinary sugar As sugar is chiefly consumed in the muscles it is supposed by some that the fault in diabetes lies in them and it has even been suggested that it is a good treatment for diabetics to do muscular work. Considering the loss of energy in the urinary sugar this hardly seems likely and it would be very valuable to have definite information.

In a debate on diabetes much attention must be given to the coma. It is even of greater importance than the glycosuria, for it is the commonest cause of death. At the present time the prevailing view is that the coma is in some way dependent upon the lævo rotary β hydroxybutyric acid which is found in the blood of a patient in diabetic coma It is excreted in the urine and even as much as 119 grammes have been said to be excreted in a day β hydroxybutyric acid exists in three forms[16] as inactive, lævo rotary, and dextro rotary, in the body aceto-acetic acid and acetone are formed from it and we usually infer its presence from finding one of these in the urine The right-handed acid is more easily decomposed in the body than the left-handed which is the acid of diabetes Two views prevail as to the way in which this acid acts to produce coma One is that it or its precursor or its derivatives are directly toxic Sternberg claims to have produced symptoms like those of diabetic coma by administering β amidobutyric acid which he regards as a precursor of β hydroxybutyric acid, but it must be remembered, as Magnus Levy[17] points out, that the amido acids found in the body are of the alpha and not the beta group and, further, I do not think that the animals which were poisoned with β amidobutyric acid by either Sternberg or Grube appear from the written description to have had symptoms very like diabetic coma Nor have these symptoms been satisfactorily produced by the administration of hydroxybutyric acid, aceto-acetic acid, or acetone, and, further, these bodies may be present without diabetic coma. The other view is that the hydroxybutyric acid, acting merely as an acid, diminishes the alkalinity of the blood, neutralising its sodium phosphate and carbonate, and hence the acid interferes with its power as a carrier of carbon dioxide, and the carbon dioxide consequently retained in the tissues is supposed to be the cause of the coma. About two facts there is no doubt. First, there is much oxybutyric acid in the blood and its alkalinity is much reduced By distilling the urine with strong sulphuric acid crotonic acid is formed if oxybutyric acid is present, the presence of the acid has been in this way demonstrated by various observers and also in the last two cases of diabetes under my care. In both these as many have found in other cases, the ammonia excreted in the urine was excessive and Herter[18] points out that the calcium and other bases in the urine are much increased when oxybutyric acid is present, showing that the lessened alkalinity of the blood has led to the calling forth of these bases from the tissues and by estimating the ammonia and other bases in the urine he believes we can approximately learn the quantity of oxybutyric acid in the blood As aceto-acetic acid is a derivative of oxybutyric acid we usually roughly infer its presence by the ferric chloride reaction Secondly, there is no doubt that the carbon dioxide content of diabetic blood is abnormally low, as shown for example by Kraus[19] My friend Dr E I Spriggs has kindly allowed me to give some results which he has obtained in the physiological laboratory at Guy's Hospital working with Dr Beddard and Dr M Pembrey The gas estimations of the blood from cases of diabetic coma gave from 14 to 23 volumes of carbon dioxide in 100 grammes of blood instead of from 40 to 50, the figures found for normal venous blood The alkalinity of the serum varied from 0 04 gramme of sodium hydrate per cent to 0 06, the normal being from 0 1 to 0 15. The blood of two diabetics who were not comatose was examined and it contained 24 and 33 volumes of carbon dioxide, so it was less than normal but not so much less as in the comatose cases. The carbon dioxide content of the urine, too, was diminished. But it has always seemed to me a far cry to argue that because there is little carbon dioxide in the blood therefore it is retained in the tissues, for blood could probably carry away in simple solution enough carbon dioxide to prevent toxæmia of the tissues by carbon dioxide, and this is quite supported by what Dr Spriggs tells me, for he and his fellow experimenters found that blood from a case of diabetes can absorb carbon dioxide about as well as ordinary blood, thus on passing carbon dioxide through diabetic blood it took up from 200 to 300 volumes per cent. of carbon dioxide This appears to show that the lack of carbon dioxide in the blood is not due to inability of the blood to take it up but may be owing to a low tension of carbon dioxide in the tissues in diabetes and especially in diabetic coma. Therefore it appears that in diabetes there is a poison which has two effects—namely, the production of coma and the lessening of the carbon dioxide in the tissues What this poison is we do not know That it merely acts as an acid is, I think, judging from experiments doubtful, but there is considerable evidence that it is closely associated in some way with oxybutyric acid (although, as already mentioned, it is very doubtful if oxybutyric acid itself, its known derivatives, or amidobutyric acid are the poison), for oxybutyric acid is always abundantly present both before and even more during coma.[20] This view that the poison is in some way closely allied to oxybutyric acid, is strongly supported by the fact that sometimes coma is benefited by giving alkalies. I have seen distinct benefit follow and Magnus-Levy records an excellent case, but as this treatment in no way destroys the poison or prevents its formation, at best only neutralising its acid properties, we must expect it often to fail, as, indeed, it does. It is interesting in this connexion to learn that Dr Spriggs did not find that the injection of alkalies increased the carbon dioxide content of the blood in two fatal cases of diabetic coma, which is what we should expect if we are right in believing that the carbon dioxide in the tissues is far below normal. I might in passing add that he found that in the last stages the administration of alkalies did not diminish the proportion of ammonia in the urine.

Much discussion has taken place as to the origin of the β oxybutyric acid It does not come from carbohydrates, for it may be present when they are withheld from the food and are absent from the urine. Until recently it was thought to come from proteids, now some suggest it is derived from fats, and again Magnus-Levy suggests that it is formed by breaking down of both fats and proteids.[21] If it does come from proteids the metabolism which leads to it is probably different from that leading to sugar, for a strong ferric chloride reaction may be present in the urine even after sugar has quite disappeared I have noticed this in children and if oxybutyric acid is derived from proteid we learn that, at any rate, not the whole of the abnormal proteid metabolism is to compensate for loss of energy in urinary sugar Until we know the source of oxybutyric acid we shall probably not know how to avoid coma Grube[22] believes it is likely to appear if butter is taken but not after pork This hardly seems likely considering how well diabetics take butter There seems no doubt that casts often appear in the urine in enormous numbers especially before coma. It will be of great interest if we can learn something of their origin and prognostic value

The sugar and oxybutyric acid in the urine are not the only evidences of perverted metabolism, for sometimes the blood is of a peculiar salmon or strawberry and cream colour, a fact quite ignored by many who write on diabetics. Usually the blood is said to be fatty Some analyses have shown a considerable amount of fat and in some of the published test-tube and all three were placed in a water bath at 40° C. After 12 hours a considerable amount of digestion had taken place, that in tube No. 1 was slightly greater than in the others. That in the tube containing salicylic acid and that in the tube containing NaCl were practically the same.

As regards the influence of salicylic acid on pancreatic digestion it must be borne in mind that the latter cannot take place in an acid medium. The addition of a trace of vinegar, of citric acid, or even of the hydrochloric acid secreted by the stomach will arrest it, and we know that the pancreatic juice is strongly alkaline and neutralises the acid contents of the stomach when they enter the small intestine. It would therefore be absurd to put salicylic acid into an artificial pancreatic digestive fluid, so we experimented with salicylate of sodium in quantities equivalent to 0·2 per cent. of the acid, using the method advised by the late Sir William Roberts for estimating the strength of amylolytic ferments and we have ascertained that salicylic acid in neutral solutions has absolutely no retarding effect whatever on the conversion of starch by the amylolytic ferment of the pancreatic juice.

We may sum up this part of our paper by stating that we have found that salicylic acid exerts about the same retarding influence on the digestive processes as do many articles, such as kitchen salt, which are always present in a mixed diet.

It is generally admitted by physiologists that the digestive enzymes such as pepsin and the ferments of the pancreatic juice act most energetically in distilled water to which the appropriate acid or alkali alone has been added and that the addition of other substances of almost any kind has a more or less retarding influence on their activity. It is obvious, however, that the *former* condition can never obtain in natural digestion, the diet of civilised man contains a multitude of ingredients most, if not all, of which would probably be found to delay artificial digestion. The question therefore is not whether salicylic acid delays digestion at all, but whether it does so to a greater extent than other bodies, such as kitchen salt, which form part of an ordinary diet.

We must point out that in making our experiments on digestion we have always given the benefit of the doubt to our opponents and have employed the strongest solution of salicylic acid which can be made in the cold, a condition which never could be present in the stomach. It is obvious that, even if the individual drank only beverages saturated with salicylic acid they would *soon* be diluted by the gastric juice, but, as a matter of fact, any beverages which we have encountered containing any such proportion of the acid were meant to be freely diluted with water before they were consumed. We *further* submit that the taste of salicylic acid is so pungent that no article which contained it in a proportion approaching one grain per ounce would command a sale unless it was intended that it should be freely diluted with water before consumption.

The second problem which we have to consider—viz., the effect produced by salicylic acid upon nutrition—is one that cannot very well be elucidated by laboratory experiments and we have felt that the only practical method of investigation was to take *it ourselves and to give it to others. One of* us took a dose of five grains of the pure acid every day for a month without any ill health ensuing and a smaller quantity given to children every day with their dinners (in a food-stuff known to contain it) certainly did them no harm. They remained as bright and active as ever and underwent no wasting. This we regard as a more convincing test than observing the result of administering to young animals milk saturated with salicylic acid. In the first place salicylic acid has a strong taste and cats are notoriously *sensitive* to an unaccustomed flavour in their food and we doubt whether the animals which have been the subjects of these experiments really took the milk provided for them at all. If this were so they lost weight from starvation and *not from* the salicylic acid which they did *not* take. In the second place salicylic acid was mixed with all the food which was given to the animals, so that the proportion of salicylic acid to their total ingestion was enormous. No one has proposed that preserved foods should constitute the sole or even a large portion of a dietary.

It is a curious circumstance that insects do not appear to be harmed by taking salicylic acid dissolved to saturation in syrup. Binz refers to its beneficial action in the case of bees when affected by 'foul brood,' a highly contagious disease caused by a microscopic schizophyte which apparently attacks the insects both internally and externally. Whole hives become infected by this fungus and become putrid. It has been found that if the bees are fed with syrup containing about 0·16 per cent. of salicylic acid the disease completely disappears and the insects recover their normal activity and vigour.

Lastly, we have to consider whether salicylic acid causes any injury to the gastro-intestinal mucosa and a very few words will serve to dispose of this question. In the first place it is well known that in the early days of the treatment of acute rheumatism with the salicylic preparations large doses of the acid were employed, but no indications of irritant poisoning are recorded. Kolbe, for instance (quoted by Binz), while *directing* attention *to its strongly antiseptic* qualities states that it is not poisonous to human beings and in proof of this he took himself and gave to other persons from 1·0 gramme to 1·5 gramme—i.e., from 15 to 23 grains—a day, in some cases for nine months together, without apparent injury, and we have already mentioned that we have observed no ill-effects from taking it ourselves or from administering it to other healthy individuals.

The objection that salicylic acid is injurious to mucous membranes appears to be based on the circumstance that it is destructive to epidermic structures when applied to them in concentrated form. We must direct attention to the fact that hydrochloric acid, acetic acid, &c., in their pure forms are not only irritant but intensely corrosive, if a drop of pure hydrochloric acid, which is a *far* stronger acid than salicylic acid, were put upon the mucous membrane of the stomach it would destroy it, and yet this acid diluted to 0·2 per cent., which is the same concentration as that of the salicylic acid found in some food stuffs, is essential to digestion, which *cannot go on* without it.

We have found another objection put forward to the use of preservatives which when reduced to the form of a syllogism is as follows:—

> Antiseptics kill protoplasm (in bacteria),
> The human cells are protoplasm,
> Therefore antiseptics kill the human cells.

It might be sufficient to reply that when the antiseptic enters the body it becomes *so much diluted that its action on* the protoplasm of the body would become infinitesimal, but a more complete answer is found by pointing out that there is a fallacy in the argument consisting in the assumption that a substance which has a deleterious action on one kind of protoplasm must act detrimentally on all kinds. Not only is there no proof of this assumption but we have strong evidence to the contrary. Among bacteria themselves there is great diversity. Some micro-organisms require oxygen for their growth while others are killed by it. Most forms of life are destroyed by arsenic, yet there is a fungus which grows in solutions of that poison. Quinine is potent to destroy the protozoa of malaria even when enormously diluted in the blood, we are not aware that it has ever been shown to act deleteriously on the normal cells of the human body. Fresh air and sunshine give vigour to all the higher forms of life, they are fatal to the germs of tuberculosis and of other diseases.

There is *one aspect of the question of the use of pre*servatives in food which has not received the attention which it deserves and which we desire especially to emphasise. As we have seen, authorities differ as to the harmlessness or otherwise of antiseptics, but they are all agreed as to the harmfulness of food in a state of decomposition. Now with regard to such luxuries as preserved fruit, non-alcoholic wines and similar articles of diet, it is clear that if the poorer classes who form the bulk of the population in our great cities are to be enabled to enjoy them they must not only be produced at a moderate cost but must be put on the market in a condition in which they can be used economically. Even if we grant that such articles as fruit juices could be sterilised without impairing their flavour and dietetic value it is clear that they would begin to decompose very soon after they were opened and the inevitable waste would be a bar to such articles being used. Further, there would always be a doubt as to whether or not the substance had gone bad and we should constantly be meeting with cases in which it had been consumed after it had gone too far. In short, we hold that it is safer to have a little more antiseptic than is absolutely necessary rather than to have too little.

It is hardly necessary to say that the stronger wines, such as port and sherry, can be used economically, owing to the manufactures, and because on sifting the evidence which has been given in various courts and before Parliamentary committees we have found that its foundations have been of the vaguest description, often depending less upon actual observations upon the results of taking salicylic acid itself than upon the results of taking other antiseptics which are supposed to be stronger or weaker—whatever these terms may mean Thus we have heard it argued that salicylic acid is ten times stronger than carbolic acid as an antiseptic, implying that it is equally or more toxic, and the natural inference would be that because 20 grains of carbolic acid cannot be taken without doing harm therefore 20 grains of salicylic acid could not be taken without doing as much or more harm which, of course, is absurd In fact, it has been so obvious that no definite evidence of harm having come of the prolonged administration of salicylic acid has been obtainable and the arguments adduced in support of its harmfulness have been so indirect and so misleading, that we make no apology for bringing this matter before our professional brethren.

In a Parliamentary inquiry one expects to find direct evidence bearing upon a matter of this kind which is of vital importance both to the public and to the manufacturer, but we have searched through the recently issued Blue-book only to discover conflicting evidence and an inconsistent "finding" that one grain of salicylic acid per pint or per pound is permissible in food stuffs We can find nothing to explain how this permissible strength was arrived at or why two, three, ten, or more grains per pint should not be used No distinction is made between the amount allowed in a pint of cider or other food stuff taken in large quantities and that permitted in a pint of any material of which perhaps only an ounce or two or even less, would be taken at a time

Some of the witnesses frankly admit that salicylic acid can be taken in doses of from five to 15 grains without any harm resulting The majority of those who are opposed to its use as a preservative are content to assert that its use, as such ought not to be permitted, without alleging any special harm which could be expected to arise. Dr J S Cameron, however, commits himself to the positive statement that it is a ' frightful depressant," but allows that injuries alleged to have followed the use of small doses were due to impurities Dr W H Corfield thinks that it is cumulative but admits that he has had little practical experience of its administration. The most elaborate attack on its use as a preservative is that of Dr J Dixon Mann, and as his is a fair sample of the kind of evidence on this point which was accepted in the inquiry we make no apology for quoting it at length He says (2611) "Last year in the summer, at lunch in the club, I took to drinking cider, and I got an acquired taste for the cider and continued taking it for many weeks I began to feel a peculiar tendency to looseness in the bowels not a diarrhœa, but a distinct looseness in the bowels, furthermore, I felt never, as it were, thoroughly relieved after motions This went on for a time and I could not understand how it was. I thought it was accidental in the first place, but it kept going on week after week I did not care to take any medicine and I began to cast about for what possibly could be the cause of it. I went over the things I had been in the habit of taking and the things I was taking at the time. I could not think of anything until it struck me about this cider, so I ceased taking the cider and in two days I was all right. I got a bottle of the same sort from the steward of the club, took it to my laboratory and found salicylic acid in it and, needless to say I have not taken cider since "

With regard to this evidence we take the liberty to point out that cider is a drink which cannot be taken with impunity by everybody and that symptoms such as those which have just been described are not uncommon among those who visit it, and take the drink of the cider making counties. We certainly have never heard of or experienced similar symptoms from the taking of salicylic acid itself or of the food stuffs which we have known to contain it. It is obvious that to establish the conclusion that it was the salicylic acid in the cider and not the cider itself which caused the symptoms complained of it would be necessary to make control experiments by taking the same quantity of salicylic acid without cider for some days and by taking cider free from salicylic acid for a similar period

It is not our intention on this occasion to approach this subject altogether in reference to the Sale of Food and Drugs Act, there are points in connexion with that Act which have a purely legal bearing For instance, we find that magistrates have not been satisfied with the evidence that salicylic acid is an injurious substance, and cases fought on this ground have been dismissed, so that now prosecutions are often based upon the fact that the foods preserved with salicylic acid are not of the nature, substance, and quality of the article demanded by the purchaser, although the law provides that an offence shall not be deemed to have been committed where any matter or ingredient not injurious to health has been added to the food or drug because the same is required for the production or preparation thereof as an article of commerce, *in a state fit for carriage or consumption and not fraudulently to increase the bulk, weight, or measure of the food or drug, or to conceal the inferior quality thereof*

We have found that it is contended that salicylic acid is injurious to health for three principal reasons (1) that it is an antiseptic and anti fermentative and is therefore liable to interfere with the digestive processes by destroying the digestive ferments, (2) that after absorption it is apt to injure the general health and to interfere with nutrition, and (3) that it is an irritant and is therefore apt to injure the mucous membrane of the stomach and intestinal canal. It will be convenient, perhaps, to consider the results of our inquiries under these headings, but, in the first place, although it should hardly seem necessary, we would point out that the greatest confusion has arisen through the use of the term "anti fermentative" which has been very loosely applied by those who have given evidence concerning this class of food preservative. In nearly every case it has been asserted that because salicylic acid is an antiseptic and anti fermentative it therefore of necessity interferes with digestion, and it is very generally inferred that because it undoubtedly in virtue of these qualities prevents decomposition, bacterial infection, and alcoholic and other kindred fermentations due to organised living bodies, it must therefore prevent the activity of the fixed or chemical ferments in the body which have for their function the transformation of starches into sugars and of proteids into peptones, or, in other words, which constitute the processes of digestion. In short, the objectors make no distinction between the processes of digestion on the one hand and those of putrefaction and fermentation on the other

In this inquiry we have nothing to do with the organised living ferments, these are certainly killed by salicylic acid and its efficacy as a food preservative depends upon that very fact, but we have found that the digestive processes will proceed in the presence of the acid even in a solution of 1 in 500 which is practically saturated.

Our first experiment was made with pepsin which, if active, should dissolve 2500 times its weight of hard boiled white of egg and the Pharmacopœia provides the following test for its activity If 12 5 grammes of coagulated and firm white of egg, 125 cubic centimetres of acidulated water containing about 0 2 per cent. HCl and 0 005 gramme of pepsin be digested together at 105° F for six hours and shaken frequently, the coagulated white of egg should dissolve leaving some flakes in the solution. Having ascertained the activity of a specimen of pepsin by this experiment we repeated it in two flasks each containing the above specified ingredients in their proper proportions but to one of the flasks 0 250 gramme of pure salicylic acid (which had previously been dissolved in eight cubic centimetres of boiling water) was added and at the end of six hours it was found that in the flask containing salicylic acid there was only a small amount of white of egg left, none being left in the other flask. This experiment was repeated three times and after one of them the residues were weighed, when it was found that there was a difference of not more than 0 024 gramme

To confirm the conclusions indicated by the Pharmacopœial test we have carried out the peptic digestion of albumin in the manner recently introduced by Mett brought to our notice by Professor Moore of University College, Liverpool The albumin to be acted on is coagulated in a glass tube open at the ends and the activity of the digestive process is readily estimated by observing the extent to which the albumin is dissolved from one end of the tube, preferably the upper end Three test-tubes were employed No 1 contained 1 per cent of pepsin dissolved in 0 2 per cent. of HCl in distilled water, No 2 contained the same with the addition of 0 2 per cent. of salicylic acid, and No 3 contained the same as No 2, only 0 2 per cent. of NaCl was substituted for the salicylic acid. A piece of Mett's albumin tube was added to each

TABLE I.—SHOWING THE CASES IN WHICH ORGANISMS WERE DEMONSTRATED IN THE BLOOD BEFORE THE USE OF ANTI STREPTOCOCCIC SERUM

	Nature of disease.	Under care of—	Blood examination during life.	Commencement of treatment and amount of serum used	Result.	Observations	Reference.
1	Sepsis from ear suppuration.	Low and Ballance.	Streptococci in the blood one cubic centimetre of the culture killed a rabbit in 48 hours	Begun at a week from onset 263 cubic centimetres in six days on one day 67 cubic centimetres.	Recovery	Drowsy and moribund.	THE LANCET March 19th 1898, p 779
	Puerperal.	Nathan Raw	Streptococci in the blood and in the placental tissue	From the fifteenth day 60 cubic centimetres in four injections		Unconsciousness temperature of 106° F pulse of 146.	THE LANCET July 9th 1898, p 81
3	Erysipelas		Streptococci swarming in the blood.	From about the sixth day 80 cubic centimetres in four days		—	Ibid.
4	Mastoid abscess and meningitis.	"	Streptococci in the blood	Within a few days 50 cubic centimetres in all		Prolonged illness	Ibid
5	Puerperal.	"	Streptococci in the blood and discharge	Within a week 50 cubic centimetres in all.		Periostitis and pyæmia.	Ibid
6			Staphylococcus aureus and albus in the blood and discharge streptococci absent	Only one injection of 20 cubic centimetres of anti streptococcic serum.	Died Post mortem staphylococci but no streptococci were present	Mixed infection	Ibid.
7	Middle-ear disease, with pyæmia.	Ramsay	Streptococci numerous with a few staphylococci on the fifteenth day no organisms on the twenty-eighth day	From the fifteenth day 255 cubic centimetres in eight days.	Recovery	Rigors and secondary abscesses	THE LANCET Oct 22nd 1898, p 1056
8	Pyæmia from the throat.	Wilde	Streptococci in large numbers in the blood which afterwards disappeared Slough in the throat with pure streptococci	From about the fifteenth day 345 cubic centimetres in nine days 10 cubic centimetres every four hours at first	"	Convulsions coma.	THE LANCET Feb 11th 1899 p 373.
9	Puerperal.	Grimsdale.	Streptococci in the blood on two occasions	From the ninth day 150 cubic centimetres in 15 days		No local treatment	THE LANCET Jan. 21st 1899 p 165.
10	"		Streptococci in the blood.	From the ninth day 170 cubic centimetres in 22 days.	"	Illness of about four weeks. No local treatment.	THE LANCET Sept 9th 1899 p 719
11	"	Lea.	Streptococci in the blood	From the tenth day	Died	Death on the thirteenth day	THE LANCET August 12th 1899 p 445
12	Septicæmia.	Bonney	? Gonococci in the blood	420 cubic centimetres in 17 days	Recovery	Probably gonococcal septicæmia.	THE LANCET June 2nd, 1900 p 1591.
13		Coleman and Wakeling	Streptococci in the blood.	10 cubic centimetres every four hours at first free use for 20 days		Delirium with a temperature of 104·6° F	Brit Med Jour vol. ii. 1896 p 647
14	Lymphangitis	Bokenham.	Streptococci and other organisms in the blood.	From the third day 102 cubic centimetres in four days	Died.	Mixed infection.	Brit Med Jour vol. i. 1897 p 1277
15	Puerperal.	Parrott.	Streptococci in the blood	From the third day irregularly 60 cubic centimetres in ten days.	"	—	Brit. Med. Jour., vol i 1901, p 145

by rigors high temperature, sweats rapidity of pulse, and delirium. The fact that so many patients have recovered from such a state when combined with living streptococci freely present in the circulation would undoubtedly point, I think, to the great value of treatment by this serum when applied under proper *conditions—that is to say* when it had been previously shown that streptococci and not other organisms were present

In Table II is a list of cases of malignant endocarditis in which the serum was used and in which an attempt was made to identify the organisms present Any evidence afforded by Table II. would at first sight seem to be unfavourable to the serum treatment, but it should be remarked (1) that several records with favourable issue are not included in the table, as, although very possibly examples of malignant endocarditis, the nature of the organism or the involvement of the valves remained uncertain, (2) that in many of the cases the serum was really inapplicable on account of the infection being either a mixed one or due to other organisms than streptococci (as in Cases 6 7 8 9 10, 11, and 16), and (3) that in those associated with pure streptococci some of the failure may be attributed to the small dosage employed, to the irregularity of its administration, and to the late date at which it was begun, more especially if it be recognised that there is at first probably a general septicæmia with subsequent infection of the valves.

It may be that malignant endocarditis, with streptococci present not only in the blood but, as a colony, in the vegetations bathed by the blood stream, is beyond the power of serum treatment in most instances, but examples such as Nos. 1 and 13 and, perhaps, 5 and 15 would seem to prove that this is not inevitably so, cases moreover, certainly vary much in the rapidity of their course and in virulence One would urge, therefore, that an earlier examination of the blood should be made in a suspicious case with irregular temperatures not amenable to ordinary treatment and that the examination should be a thorough one, not merely of a drop or two of blood, but of half a drachm or a drachm, incubated in sterile bouillon at the earliest moment, and that if streptococci be then found, freshly prepared 'polyvalent" serum should be used very freely and continuously in doses of 10 or 20 cubic centimetres twice a day It will be seen that in some of the cases recorded in Table I which ended successfully the amount of serum injected was very large indeed.

Moreover, as it is clear from all the more recent records large amount of antiseptic—namely, alcohol—which they contain, and the need for antiseptics, such as salicylic acid is largely due to a commendable desire on the part of a large proportion of the public to have wholesome and agreeable beverages free from the risk of the moral and physical evils which too often attend the use of alcoholic drinks

We desire to make it clear that we are not now discussing the recommendation of the Commission that the law should be altered so as to require manufacturers to state the nature and amount of the preservative, whatever it may be, which is present in certain articles sold. The practical point at issue between us and the Commission is that the latter, though allowing the use of salicylic acid would limit it to one grain per pint, while we maintain that if a larger proportion is necessary for the manufacture and preservation of the article there is no valid reason why it should not be employed It is scarcely necessary to insist on the fact that if a preservative is to be used some articles will require more of it than others and it by no means follows that the article most difficult to preserve is the least valuable and nutritious Thus, to take an extreme case, let us suppose that there is a demand for a temperance beverage with a flavour of raspberries Such a beverage can be produced in a variety of ways It may be prepared by pressing out the juice of raspberries with such additions as are necessary to render it sufficiently fluid and agreeable to the taste, or it may be prepared without the help of any fresh fruit at all, using a chemical body, the so called essence, to give the distinctive flavour It is clear that the latter being free from nitrogenous matters will be much more easily preserved than the former, though the former would certainly be the more agreeable beverage and would approach much more nearly to the characters of natural fruit We are convinced that one effect of the arbitrary limitation of the amount of preservative allowed will be to force manufacturers of the so called non alcoholic fruit wines and other temperance beverages to employ artificial flavouring bodies prepared in the laboratory instead of the natural juice of the fruit One noted firm, harassed by successive prosecutions has written to us as follows "We are now in the strange predicament of being compelled to discontinue the use of the nutrient article and use a substitute rather than that an antiseptic be used. But the game of fighting when, win or lose, one cannot recover expenses, is too one sided to be interesting, especially as the other will pay us at least quite as well." We have also good authority for alleging that another result of these prosecutions is to set manufacturers to work to discover antiseptics which cannot be recognised by the analytical chemist and we are informed that such an antiseptic is already employed by one firm. It is surely in the interests of the public that an antiseptic should be employed the presence and amount of which can be determined and the properties of which are generally known rather than one which cannot be detected when it is present and of the properties of which we know nothing

To refute a popular error is often a thankless task, to refute an error sanctioned by tradition and authority will generally excite obloquy and opposition. When, however, an error is maintained as if it were the result of the deductions of the most enlightened scientific investigations and is supported by names eminent in science and medicine the task of opposing it is not alone thankless and unpopular but is likely to be stigmatised as retrograde and reactionary Nevertheless, we have felt it to be our duty to place on record our conviction that the allegations which have been made against the employment of salicylic acid as a preservative in moderate quantities cannot be maintained. We challenge the opponents of its use to bring forward a single instance in which it can be shown that bodily injury has resulted from its employment in such a manner, and we deny that in the proportion in which we have met with it in articles submitted to us for examination it could be taken by any rational beings to such an extent as to do them any harm whatever We further maintain that the use of this substance enables manufacturers to place on the market wholesome, agreeable and inexpensive articles of food which form an acceptable and beneficial variety in the diet of persons who cannot afford more costly luxuries and which, above all, supply the place of intoxicating drinks This is the position which we maintain and we state it after mature consideration and with, we trust, an adequate sense of responsibility

CONCERNING ANTI-STREPTOCOCCIC SERUM AND ITS USE IN MALIGNANT ENDOCARDITIS

BY CYRIL OGLE, M B OXON, F R C P LOND,
ASSISTANT PHYSICIAN TO AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, ST GEORGE'S HOSPITAL LONDON

THE therapeutic value of injections of anti streptococcic serum may be said to be still uncertain. This seems to be due, in great part, to the indiscriminate way in which it has been tried and the results have been recorded It appears to be established, by laboratory experiments, that this serum (1) is of such a nature as to be of value against streptococci only, and probably only against that variety or those varieties of streptococci by means of which it had been prepared, and (2) that it leads to the destruction of these organisms and does not merely neutralise toxic products, as does anti diphtheritic serum, for example, in the case of diphtheria—that is to say it is directly or indirectly germicidal and not antitoxic in its action In order to demonstrate the value of this treatment, therefore, it should be shown that the above conditions have been fulfilled. In most examples recorded of its use this has not been kept in mind

Many striking recoveries from grave conditions of sepsis treated by injections of anti streptococcic serum are to be found, but they are chiefly puerperal cases evidently due to sapræmia resulting from the absorption of toxins from the foul interior of the uterus, and their recovery may as properly be attributed to the local measures of disinfection adopted as to the subcutaneous injections of the serum Others are, in similar fashion, complicated by the presence of a local abscess, subcutaneous, about the appendix, or in connexion with the ear also amenable to direct local treatment Others, again, are most probably a general infection with gonococci, which, though severe, often recover under ordinary general treatment.

The evidence in favour of the serum treatment in the case of erysipelas is, perhaps, more convincing, as that disease is known to be associated with streptococci of some variety or of particular virulence and the treatment is usually only applied to severe cases But one would like to know whether the graver general symptoms met with in certain examples of this disease are due to the circulation of cocci in the blood stream, as, if so, the serum treatment would be the more clearly indicated and cases of recovery would be the more striking

As regards malignant endocarditis, local treatment of the valves is unfortunately impossible and the only way, during life, of proving the presence of streptococci is by finding them in the blood and the only strict proof of the efficacy of the serum treatment, or of its failure, would be by recovery of the patient after thus finding them or by displaying them after death in the blood and in the vegetations The examples of malignant endocarditis treated with this serum appear to be few and the number investigated in this manner to be very few It is possible, of course, that some cases ending in death, although examined for bacteria, have not been published and this is to be regretted.

In this connexion it seemed that it might be of interest to collect and to analyse the cases of treatment by anti streptococcic serum published, or alluded to, in THE LANCET and in the *British Medical Journal* during recent years (from 1896 to 1901 inclusive) They amount to between 100 and 110 in number, including more than 70 recoveries, and on reading them it is difficult to avoid coming to the conclusion that the injections really contributed greatly to the favourable results recorded, but as no examination was made in most cases to show the presence or absence of streptococci in the blood stream, nor even in the local condition, these cannot be adduced as very strong evidence of the value of the serum treatment, nor can the deaths be attributed to its failure In a few cases streptococci were shown to be present in the local condition, *although the blood* was not examined during life, and here the evidence in favour of the injections is more conclusive. In 13 cases streptococci were found during life, even in the blood stream, as shown in Table I

It is almost impossible by means of a table to convey an impression of the gravity of these latter, but, as might be expected, they were all severe and were marked often that these subcutaneous injections produce no serious symptoms, if it result that the examination of the blood be negative (as often happens) this fact should not, perhaps, be held to contra indicate the employment of the serum in a case with symptoms of sepsis and implication of the heart, especially if there is a probability from collateral evidence, such as the history of any external suppuration or dental caries or ear disease, or of absence of gonorrhœa or pneumonia, that streptococci are really the organisms concerned Of course, merely an ill defined systolic murmur, with an irregular temperature, does not constitute such a case. At the same time, it is obvious in Table II that staphylococci, either by themselves or together with streptococci, frequently cause the infection (see Cases 6, 7, 8, 9, 10, and 11)

It may perhaps be worth considering whether an anti staphylococcic serum, if such be procurable, should not rather be used in an indeterminate case or be used in conjunction with anti streptococcic serum. The only example of the use of anti staphylococcic serum in these conditions which I have come across is that of Moritz[1] and the patient recovered, but the diagnosis of the organism present had not, I believe, been confirmed previously by a blood examination, although the evidence of implication of the valves seems to have been certain.

If any conclusions, therefore can be drawn from these two tables they would, perhaps, be (1) that the gravest symptoms, combined with streptococcic infection, even of the blood stream, are not incompatible with recovery if treated by injections of anti streptococcic serum, (2) that this is true also in malignant endocarditis, but that here the chances are probably less favourable on account of the colony of micrococci involved in the vegetations in constant contact with the blood stream, (3) that in malignant endocarditis staphylococci are frequent, or a mixed infection of staphylococci and streptococci, and (4) that if an examination of the blood be negative it would be prudent, therefore, to use injections of anti staphylococcic together with anti streptococcic serum

Gloucester-place, W

HOW TO PREVENT THE SPREAD OF PELLAGRA IN EGYPT[2]

By F M SANDWITH, M D DURH., F R C P LOND,

PROFESSOR OF MEDICINE MEDICAL SCHOOL CAIRO SENIOR PHYSICIAN KASR EL-AINI HOSPITAL, CAIRO

IT is now ten years since I first discovered the presence of pellagra as a frequent accompaniment of ankylostomiasis among the poorer peasants of Lower Egypt Since then I have seen 1000 cases, most of which have passed through my wards at Kasr el Aini Hospital. Thanks to the courtesy of Dr J Warnock I have also had the opportunity of visiting most of his pellagrous patients in the lunatic asylum, who number about 40 every year These figures are sufficient to show that the disease is prevalent among hospital patients, the poorest members of whom live on diseased maize, which they eat at home because it is too bad to command a price in the local market By far the greatest number of hospital patients are men between the ages of 20 and 40 years, when they ought, of course, to be in the prime of life, working as agricultural labourers or serving their country in the police, the army, or in other ways. I have never yet found a single patient who was acquainted with the disease or who understood that an eruption of the skin was the outward sign of a chronic disease of the brain and spinal cord.

The ignorance of pellagra in Egypt is so great that I thought it would be interesting to examine some of the labourers actually at work in the fields to see if any of them showed signs of the disease. In June, 1902, I examined 315 men living in 11 different villages in the province of Gharbieh, 114 of them or 36 per cent., showed signs of early pellagra. In one village where the inhabitants are especially well to-do because they get regular pay throughout the year from the Domains Administration there were only 15 per cent. of pellagrous men, while among the men of the village which has the reputation of being the poorest the percentage rose as high as 62. Yet all these men stoutly denied that they had anything the matter with them and the overseers in charge of them stated that the pellagrous could all do a fair day's work On the same day I examined 23 young girls who were working at the threshing floor or picking eggs off the cotton plants and again I found that 30 per cent. of them were already pellagrous On a previous occasion I had examined 139 presumably healthy peasants in the province of Sharkieh and had found 50 per cent. of them to have pellagra If these figures are in the least typical of the state of the male inhabitants in Lower Egypt it is quite time that something should be done to disseminate information on the subject and gradually to teach employers of labour and peasants that the early symptoms of the disease can easily be recognised, that they will then yield to treatment, but that, if neglected, the symptoms are of a progressive nature and will end in insanity or in general debility which entirely unfits the individual for work I venture to recommend that the village authorities of Lower Egypt (mudirs, omdehs, sheikhs, &c.) should be informed by the usual methods of the Ministry of the Interior that good maize is an excellent food but that the habitual use of bad maize produces a disease affecting not only the skin but also the digestive and nervous systems There are many other points connected with improvement in hygiene, but it seems useless to insist on these so long as we have to deal with an agricultural population which is entirely unable to read

The number of markets where maize is sold is so great in Lower Egypt that it is impossible at present to make any proposal for inspecting them, though I think that the local authorities might be informed that it is improper to allow obviously diseased maize to be exposed for sale But it is not the worst maize which finds its way to the market, for the worst samples cannot command a price It is the poorest peasants who are the chief offenders, for at the end of each year their custom is to take, in lieu of some of their wages, a piece of land which they cultivate for themselves with a crop of maize. The most careless of them sow diseased maize seed, gather the crop before it is ripe, store it in damp places before it is properly dried and worst of all, preserve the cobs within their sheaths in order that the sheaths may protect the grain from being eaten by the *Sitophilus granarius* I have several times laid stress upon the fact that it is the inhabitants of Lower Egypt who require special protection in this matter Their maize crop in 1902 is calculated by the Ministry of Finance at nearly 900 000 acres The peasants in Upper Egypt are equally poor and equally ignorant, but they are saved from pellagra with certain exceptions because their staple diet is not maize but millet. The maize crop of Upper Egypt is about 100,000 acres, of which nearly half is grown in the Fayoum.

There is one other question which should not be neglected and which could be easily regulated by the Government. I refer to the maize imported for consumption in Egypt from other countries especially from those which we know to be affected by pellagra, such as Roumania and Turkey All imported maize should be examined in Alexandria before it is allowed to be sold in the market there.

Cairo

THE ETIOLOGY OF SLEEPING SICKNESS[1]

(PRELIMINARY NOTE.)

BY ALDO CASTELLANI, M.D FLORENCE.

SEVERAL germs have been described as the cause of sleeping sickness Cagigal and Lepierre in 1897 announced that they had isolated a bacillus from the blood of a patient suffering from sleeping sickness, which when injected into animals was able to reproduce the disease, but these experiments of the two Portuguese medical men were not confirmed later by Brault and Lapin. Next, Marchoux, basing his statements on the following observations, is of the opinion that sleeping sickness is due to Fränkel's diplococcus. At the post-mortem examination in a case of sleeping sickness where the patient was suffering also from

[1] A paper read before the Royal Society and published in THE LANCET by request.

TABLE II —MALIGNANT ENDOCARDITIS IN WHICH ANTI STREPTOCOCCIC SERUM WAS USED AND IN WHICH AN ATTEMPT WAS MADE TO IDENTIFY THE ORGANISMS PRESENT

Case	Nature of disease	Under care of—	Blood examination during life	Commencement of treatment and amount of serum used	Result	Observations	Reference.
1	Endocarditis	Sainsbury	Streptococci in the blood before treatment absent afterwards	10 cubic centimetres every other day from two months after onset 70 cubic centimetres in 18 days	Recovery	Alteration in murmurs	THE LANCET Oct. 17th 1896 p 1079
2	"	Fox	No bacteria found in the blood but examination made after 12 injections of serum	20 cubic centimetres daily from about the twenty first day 160 cubic centimetres in 10 days	Died	Streptococci in vegetations	THE LANCET Feb 20th 1897, *p* 520
3		Pearse.	No bacteria in the blood but examination made after 16 days of treatment	Up to 20 cubic centimetres daily from about the fourteenth day 100 cubic centimetres in 11 days	Recovery	Alteration in murmurs and pericarditis	THE LANCET July 10th 1897 p 92.
4	"	Washbourn.	No bacteria found in the blood.	20 cubic centimetres daily from about the sixth week (?) 1030 cubic centimetres in 60 days	"	Development of basic diastolic murmur	THE LANCET Sept. 18th 1897 p 707
5	"	Michell Clarke.	No bacteria found in *the blood*	30 cubic centimetres *daily from about (?)* the sixth week 232 cubic centimetres in all.	"	Illness of three months variation of murmurs temperature of 103° F	THE LANCET July 21st 1900 p 168
6		Abram	Streptococci and staphylococci in the blood	10 cubic centimetres daily of anti streptococcic serum 100 cubic centimetres in 10 days	Died	Streptococci had disappeared post mortem but staphylococci were present	THE LANCET Feb 25th 1899 p 515
7	"	Rogers	Streptococci in pure culture in the blood on two occasions	10 cubic centimetres daily from two months only 50 cubic centimetres used	"	Staphylococci with streptococci present post mortem	THE LANCET June 10th 1899 p 1558.
8	"	Lermitte and Fox.	Staphylococci but no streptococci in the blood	10 cubic centimetre doses of anti streptococcic serum 149 cubic centimetres in seven days	"	Vegetations not examined for bacteria.	THE LANCET Nov 4th 1899 p 1225.
9	"	Mackie	Two colonies of cocci in the blood	20 cubic centimetres daily *from* the twenty first day 180 cubic centimetres in nine days	"	Staphylococcus albus in the vegetations and spleen post mortem	Brit. Med Jour vol i 1899 p 142.
10	"		Staphylococcus aureus in the blood sputum and urine	20 cubic centimetres of anti streptococcic serum one injection only given		Staphylococcus aureus in pure culture post *mortem acute case*	Ibid
11	"		No examination of the blood	20 cubic centimetres only one injection used	"	Vegetations with short streptococci and some staphylococci post mortem mixed infection	Ibid
12	"	Ewart	Blood examination negative.	80 cubic centimetres in seven days from eighth day after embolism	"	Development of aortic diastolic murmur Rapid case Vegetations not examined post mortem	Brit. Med Jour vol ii 1900 p 906
13		Laignel and Lavertine	Short streptococci and a few staphylococci in the blood	20 cubic centimetres daily from the fourteenth day	Recovery	Diffused systolic murmur	La Presse Médicale, Paris 1897 tome iii. p 193.
14	"	Cavafy	Streptococci in pure culture in the blood	10 cubic centimetres every other day from the seventeenth day (?) only 120 cubic centimetres in all in 20 days	Died	Streptococci almost pure in vegetations and *blood post* mortem	St George's Hospital Medical Register 1898 No 556.
15	Septicæmia and probably endocarditis.	Ewart	Streptococci in the blood	From about a month after the onset 200 cubic centimetres in 21 days	Recovery	High temperature sweating thrombosis of the veins swelling of the joints systolic murmur which disappeared	St George's Hospital Medical Register *1898, No* 1020
16	Endocarditis	Owen	No examination of the blood.	23 cubic centimetres in all in the last week of life Indefinite onset of illness	Died	Streptococci in the vegetations and the blood with many diplococci (? pneumonic) post mortem	St George's Hospital Medical Register 1900 No 1605
17		Rolleston.	No bacteria found in the blood	From about six weeks after onset 30 cubic centimetres in all in 11 days	"	Vegetations on the valves pure streptococci in the spleen cerebral and other embolisms post mortem	St George's Hospital Medical Register 1900 No 65
18	"	Curnow	Streptococci in the blood	150 cubic centimetres in all		Diplococci from the heart post mortem	Lumleian Lectures 1898 (Sir *R D Powell*)
19	"	Cooper and Ogle	Streptococci in pure culture in the blood	Not before the sixth week 110 cubic centimetres in 27 days	"	Aortic, diastolic and changing mitral murmurs hectic temperature and embolism	Brit Med Jour vol. i 1902.

single members present much larger dimensions and sometimes (as Stoltz has already observed in streptococcus lanceolatus *Centralblatt für Bakteriologie*, Band xxiv , S. 337) they present the form of a club.

3. *Gelatin.*—The description given is not to be changed.

4 *Agar*—As regards the agar stab, I do not modify anything

Agar streak.—Instead of the description I gave I would put simply the following The growth is generally much more vigorous than the typical streptococcus pyogenes and the streptococcus lanceolatus, the colonies showing a marked tendency to coalesce. Still in some cases the growth may be much more delicate than usual and the colonies may remain separate.

5. *Bouillon*—I have nothing to change, but I would add the following The bouillon tubes presenting a general cloudiness at a microscopical examination show chains and diplococci forms sometimes diplococci forms only

6 At the end of the paper, where I make the differential diagnosis between my streptococcus and the other varieties of streptococci, I have written in my note that the streptococcus which I have described is differentiated from the streptococcus lanceolatus because it grows well on gelatin , *besides, in the agar cultures of my germ I have never seen the dew drop like appearance of the agar culture of the streptococcus lanceolatus* I should perhaps like to omit from my note the last sentence, which I have italicised, or at least to modify it, because some recent experiments have shown me that the agar cultures of my germ may show in *rare cases and special circumstances* (very old agar, &c.) a certain likeness to the agar culture of the streptococcus lanceolatus. Besides, I think, the fact that my germ grows well on gelatin is quite sufficient to distinguish it from the streptococcus lanceolatus

ON PROLAPSUS UTERI, WITH SPECIAL REFERENCE TO AN OPERATION FOR REPRODUCTION OF THE SACRO-UTERINE LIGAMENTS[1]

BY E STANMORE BISHOP, F R C S Eng ,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

[After quoting part of a paper by Mr F Bowreman Jessett which appeared in the May number of the Journal of the British Gynæcological Society in 1901 on the same subject and thus pointing out that to that author belonged the credit of previously devising and publishing an operation upon the sacro-uterine ligaments, Mr Stanmore Bishop said —]

But while this is the case the procedure which I advocate and which I desire to bring forward now differs from the one which Mr Jessett describes not only in some points of technique, but essentially in its aim and in the result produced. Mr Jessett seeks to produce, and succeeds in producing a return of the uterus to its normal level in the pelvis and fixes it there—fixes the cervix to the sacrum behind and the fundus to the abdominal wall in front. So long as the adhesions which he makes between the structures hold good the uterus is rigidly retained in position and I conceive is unlikely ever again to prolapse but the aim and result of his operation are firm fixation with little or no movement afterwards of the organ so fixed The aim of the operation which I am about to describe is quite different. It is to obtain, as nearly as possible, a *return to the normal condition* I should like to emphasise this phrase "a return to the normal condition' because I believe that we have a right to expect such a return at the present time in these cases. It is to be noted that we have to deal in this deformity not with the ravages of disease, leaving behind them alterations in structure which render such a return impossible, or with actual losses of tissue which cannot be replaced, but with the results of injury or traumatism, which are not necessarily followed by either of these—which leave the parts affected in new relations to one another, it is true, but beyond this in most cases but little altered intrinsically and therefore simply necessitating the repair of the results of such injury in order to restore the patient to the *status quo ante*, and this I believe in the majority of instances to be perfectly practicable.

Therefore we need first of all a definition of the *normal* uterus and I offer this as practically useful for the purposes of this paper The normal uterus is one which is free to move in every direction within certain limits but not beyond, and which is capable of development in all its parts during a succeeding pregnancy In order to make what follows clearer permit me very briefly to draw attention to some points in the anatomy of this region The general anatomy is, of course, perfectly well understood, but there are certain things upon which fresh light has lately been thrown and these are, I think worth consideration The uterus is a muscular body with muscular offshoots, ending in tendons the latter blending with the periosteum of the pelvis at four points of which the two anterior are nearly opposite to the two posterior These muscular offshoots are much longer in proportion to their width and so permit of the free movement of the uterus within certain well defined limits. They are the true ligaments of the uterus, and by their periosteal attachments they support the uterus at a normal level and prevent prolapse. These true ligaments are the round or fundo-pubic ligaments in front and the sacro-uterine, sacro-genital, recto-uterine, or retro-sacral—for by all these names they are described by various authors—ligaments behind. Attached to and swinging from, the periosteal insertion of these true ligaments to the bony pelvis, the uterus is free to move within certain limits but not beyond It is also perfectly free to develop in all its extent during pregnancy If we wish to restore the uterus to a normal condition we must therefore so act as once more to leave it *free to move within normal limits, but not beyond, and to develop in its whole extent during any succeeding pregnancy.*

I need say nothing of the round ligaments. Their anatomy, position and use are all perfectly well understood, but it may surprise some that I should describe the sacro uterine ligaments as musculo-tendinous offshoots of the uterus In old works on Anatomy and in most of later date, these ligaments are figured and described as mere folds of peritoneum In "Grey's Anatomy," last edition, 1901, they are still so described. In the eighth edition of 'Quain's Anatomy" there is exactly the same description, but this is altered to some extent in the last, the tenth edition, edited by Schäfer and Thane. In this, after describing the fold of peritoneum, it is said "This fold contains a variable amount of fibrous tissue and some non striped muscular fibres forming the utero-sacral ligament."

Schultze, in 1888, in his work on "Uterine Displacements," p 2, says "These folds of peritoneum [referring to the folds of peritoneum surrounding the uterus] contain muscular bands arising from or inserted into the uterus and in the ligamenta rotunda and ligamenta Douglasii, at the anterior and posterior edges of the folds these bands are particularly well developed From the posterior surface of the uterus, a little below the junction of the cervix to the body of the organ, the muscular bands in the folds of Douglas pass to the lateral parts of the sacrum, nearly at the level of its second vertebra. The upper, so-called posterior, insertion of these muscular bands varies considerably, though it would seem that they always lose themselves in the muscular wall of the rectum and in the subserous connective tissue. The anterior or lower insertion is formed by some muscular fibres from each side coalescing behind the uterus and forming a single unique muscle, called by Luschka the musculus retractor uteri In the gravid or puerperal uterus the normal hypertrophy of the muscular tissue of the uterus extends to that of the folds themselves " But undoubtedly the best account of them is to be found in a paper contributed to the January number in 1902 of the *Journal of Anatomy and Physiology* by Professor Dixon and Professor A. Birmingham. They say "The sacro-genital ligaments are two bands of mixed fibrous and muscular tissue which pass from the region pericarditis he found Fränkel's diplococcus in the exudation of the pericardium. It is worth noting that he found the germ in the pericardium only and not in the cerebro spinal fluid or in any other situation In a second case complicated by chronic rhinitis and suppuration in the sinus frontalis the secretion of the nose showed the same micro-organism. Besides these two observations, to which I do not think a great amount of importance can be attached, Marchoux was brought to this hypothesis by having noticed that sleeping sickness sometimes developed in people who had suffered from pneumonia.

---

[1] A paper read before the British Gynæcological Society on Dec. 11th 902.

Lately there have been the bacteriological researches of the Portuguese Commission and those of Dr Broden The Portuguese describe a germ (a diplo streptococcus, to use their denomination) which they state they have found constantly in the cerebro-spinal fluid at the post-mortem examination of their cases They state that they have also found the same organism in patients during life constantly in the blood of cases examined for this purpose and very frequently in the cerebro-spinal fluid taken by lumbar puncture. The characteristic of their organism is that it does not usually grow on the ordinary culture media like agar, glycerine agar, &c, and not at all on gelatin The Portuguese do not mention having made any attempt to see if the blood of patients suffering from sleeping sickness has any agglutination power on their germ

Dr Broden, director of the bacteriological laboratory at Leopoldville, describes as the cause of the disease a bacillus which is slightly motile, producing a pellicle in bouillon and growing abundantly on potatoes He was able to find the germ constantly in the blood of all his patients The bacillus was not agglutinated by the blood of patients suffering from sleeping sickness

In this short note I propose to give only a brief account of my experiments and researches. I must state first that I have never been able to find any of the germs described by my predecessors but, on the other hand, I have found an organism which I think I have good reasons to consider to be the cause of sleeping sickness I have grown it with absolute certainty (and always pure) in eight out of ten post-mortem examinations, from the cerebro-spinal fluid, and from blood of the heart taken with aseptic precautions. *In vitâ* I have found it only once in the blood, but I have grown it in two cases out of three from the cerebro spinal fluid removed by lumbar puncture.

Description of the organism.—The germ may be considered as a distinct variety of the streptococcus group The microscopic appearance is very variable, depending on the different media on which the germ has been cultivated and on the different times of growth, &c, all transitions from long chains to typical diplococci being seen The form and size of individuals are also, within certain limits, variable Frequently about the chain and the diplococcus forms well defined mucoid capsules (*Schleimhullen*) are seen, and in hanging drop preparations the short chains and the diplococci forms show a well marked Brownian movement.

Staining properties —It is easily stained with the ordinary solutions of the different aniline dyes

Cultivation —*Gelatin* —Growth occurs very well on gelatin at a temperature of about 22° C and also below In a stab culture the stab is generally thread shaped, although sometimes it may appear a little granular, the surface growth is very slight. In streak cultures the colonies coalesce, forming a mass with a fine granular surface and sometimes wavy borders In some few cases after five or six days I have noticed a very slight liquefaction of the gelatin.

Agar —In a stab culture growth takes place luxuriantly along the stab, the surface growth being generally more delicate. In streak cultures in most cases the growth is very vigorous, the colonies not remaining separate but coalescing into a whitish mass with granular surface and wavy borders. In none of the cultures is the typical growth of the streptococcus pyogenes seen—viz., the collection along the stab of small circular semi translucent discs, which show a great tendency to remain separate. Still, in rare cases—especially if the agar is old—the growth may be much more delicate and the colonies may remain separate. The water of condensation shows, as a rule, a slight whitish deposit

Glycerine agar —The growth is the same as on agar, but rather more delicate.

Sugar agar —There is no gas formation.

Litmus agar —The colour of the medium does not change

Potatoes —There is very slight growth, sometimes none.

Bouillon —The appearance of bouillon cultures varies greatly In the majority of cases the bouillon remains clear and there is a flocculent and sometimes sandy sediment. In these cultures one generally finds long chains on microscopic examination. In some cases the bouillon is cloudy, with little or no sediment, and in cultures of such an appearance microscopical examination will often show the cocci arranged in pairs and in short chains. The same strain of germ sometimes will make the bouillon cloudy and sometimes not. I once inoculated a tube of bouillon from an agar culture and obtained a bouillon culture with no turbidity and with a well marked flocculent sediment. Two weeks later I inoculated another tube of bouillon from the same agar culture, but this time the bouillon became cloudy and the sediment was very slight. In a strongly alkaline bouillon it is easy to obtain a diffuse cloudiness. The same observation has been made by Waldvogel with other varieties of streptococci.

Serum —There is good growth, but more delicate than in agar

Milk.—There is no coagulation. This is an important character of differentiation from the streptococcus pyogenes, as well as from Fränkel's diplococcus, both of which produce coagulation (Kruse, Pansini Lehmann)

Relation to oxygen —The micro-organism is a facultative anaerobe.

Agglutination.—Experiments have just been begun to determine if the germ is agglutinated by the blood of patients suffering from sleeping sickness. The experiments are still too few for one to come to any definite conclusion, but as far as they have gone the results have been very satisfactory

Conclusions —From the description just given I think that this germ must be considered a new variety of streptococcus. Every bacteriologist knows how difficult it is to differentiate sharply the varieties of streptococci on account of the numerous transition forms that occur, even a sharp separation between the streptococcus pyogenes and the streptococcus lanceolatus[2] (Fränkel's diplococcus) seeming to many observers to be impossible Still, I think that the streptococcus I have found may be regarded as a distinct variety The cultivation on gelatin is sufficient to differentiate it from the streptococcus lanceolatus, as the latter does not grow at all, or only very badly, on that medium. Besides, the agar cultures of my streptococcus have not the dew drop-like appearance of those of the streptococcus lanceolatus. It is differentiated from the streptococcus pyogenes by its much more vigorous growth on all media, and especially on agar, by the tendency of its colonies to coalesce, and by the non coagulation of milk. As regards the diplo-streptococcus of the Portuguese I do not think any confusion can arise The Portuguese state that the culture of their germ generally failed every time on the usual media like agar, gelatin agar, &c and with gelatin they never succeeded in obtaining cultures

The streptococcus that I have described grows very well on gelatin and on all the other usual media. This character differentiates the organism also from the streptococcus intracellularis (diplococcus intracellularis of Weichselbaum) which does not grow at all, or very badly, on gelatin, and also, according to some observers (Lehmann), on cow serum.

My experiments are not complete and they are not yet numerous enough, still, having grown my germ (always pure) in eight out of ten post-mortem examinations and having grown it from the cerebro spinal fluid taken *in vitâ* by lumbar puncture in two out of three patients and having also had, as far as I have gone, very satisfactory results as regards agglutination, I think that I am not wrong in stating that according to all probability the cause of sleeping sickness is to be looked for in this germ. I think that this organism is a distinct variety of streptococcus, to be classed between the streptococcus pyogenes and the streptococcus lanceolatus (Fränkel's diplococcus), and it might be called the streptococcus of sleeping sickness

Additions and Modifications to my Preliminary Note.

1 Counting the last post-mortem examination I have grown the micro-organism in nine out of 11 post-mortem examinations.

2 *Microscopical appearances* —To be added, the following In old cultures involution forms are produced, frequently

---

[2] I follow the classification and nomenclature of Lehmann (Lehrbuch der Speziellen Bacteriologischen Diagnostik)

as a last resource and operations were planned and instruments such as the old hernia knife and dissector were constructed for that one all important purpose—to avoid opening the peritoneal cavity Naturally in those days no attempt was made to interfere with the ligaments and all operators busied themselves with attacks upon the uterus through the one avenue open to them—the vagina—and upon the one structure with which they believed that they could safely deal—the vaginal mucous membrane. It was not then a question as to what was the ideal treatment, it was a question of what was possible under the then existing conditions

When an attempt was first made to shorten elongated and lax ligaments, those the ends of which lay outside the peritoneum and could be dealt with without invading that cavity were naturally the first to be attacked and the operation for shortening the round ligaments was devised. In cases of retroversion or retro-flexion it has done extremely good work and will continue to do so, but it is curious to note that the importance of the genito-sacral ligaments was fully recognised by Alexander himself who instituted this operation, although he and those who followed him made no effort to deal with them by operation In his Practical Gynæcology,' p 61, he says "The Hodge or the Hodge and stem, according to the nature of the case, are always introduced just before the operation is commenced. The Hodge should be fairly large so as to push the cervix well back and relax the posterior uterine ligaments. The stem is removed at the end of the third week. Where there is a weakened perineum a tendency to cystocele or rectocele or distinctly relaxed retro-sacral (*sic*) ligaments the perineum must be fortified at the same time that the round ligaments are shortened or a Hodge's or other pessary as an inferior support will require to be permanently worn.'

Useful as this operation on the round ligament is in cases of retro-deviation, its inefficiency in cases of prolapse and procidentia is evident *a priori* from the very conditions of the problem involved, and is equally evidenced in practice by the numerous fixations which have been in vogue of late years. A pull from the uterine cornu towards a fixed point in the pelvis on the same or but very slightly higher level can never raise the whole body of the uterus to any great degree, still less if the posterior supports are gone can it raise and carry backwards the cervix. It will then simply draw the uterus forwards towards the pubes and so place it in a still more favourable position for further descent, and, recognising this, surgeons who had overcome by that time all dread of an open peritoneum seized the uterine body and drawing it bodily forwards and upwards, fixed it to the nearest point which offered resistance, the abdominal wall above the pubes But such ventrofixation materially interferes with the proper development of the anterior uterine wall in any subsequent pregnancy and so it became a matter of great importance to show patients who in spite of this had carried a fœtus to full time development. Several such cases are now on record, but whilst it has thus been shown that such a result is possible, cases are also on record in which abortion has occurred repeatedly, others in which the resulting parturition has been greatly impeded, and others in which death has resulted. It is human nature that successful cases should be emphasised and that those which have ended badly should be frequently unreported The more honour to those authors who have faithfully recorded their failures but none the less the departure from a normal condition induced by this operation and its results stands out clearly No operator who has performed a ventrofixation, and still less the practitioner to whose unlucky lot it may fall to attend a patient through the succeeding period of irregular dilatation of the uterus during pregnancy and the equally risky parturition can feel happy or secure until this severe test is well over however triumphant they may appear afterwards. If nothing nearer to a return to the *status quo* is possible, the method with all its drawbacks may in some cases be justified—in women past the child bearing period, for instance—but if better methods can be carried out, methods which attain more nearly to a restitution of the prolapsed organ to its original position and condition, then the supposed necessity of this plan loses its *raison d'être*

I have myself performed a large number of ventrofixations and besides the objections already mentioned another has been strongly impressed on my mind. The portion of abdominal wall to which the uterus has been attached, although relatively a fixed point, is not so absolutely Months after the fixation has been carried out the area of fixation will be found to have sunk inwards, having been drawn backwards and downwards by the weight of the attached organ, which will have sunk again to a much lower level than that at which it appeared at the time of operation to be located, so that the final result is, even so far as the mere elevation is concerned, not so satisfactory as at first would seem to be the case. The bladder in many of my cases also was compressed to some extent, its capacity was decreased, so that the patients were troubled by undue frequency of micturition and an inability to restrain themselves for any length of time when desire to urinate arose.

I do not mention vaginofixation except to condemn it. I have practised it in one case but should never again attempt it The principle upon which it is based is, to my mind, false and its results, so far as I have seen them, are deplorable

There is, moreover, one comprehensive objection to all these operations and a very forcible, if not a fatal, one. Consider for a moment the symptomatology of this condition. In the very earliest period of prolapse and increasing *pari passu* with it pain and a sense of dragging weight are felt in the lumbo-sacral region. The uterus as it descends usually becomes more bulky and many of the discomforts experienced are attributed to its increased weight This is doubtless true but for the full explanation I conceive that we must go still further back. The nerves of the uterus are derived from the inferior hypogastric and spermatic plexuses of the sympathetic system, both of which lie on the posterior concave wall of the pelvis behind the peritoneum and closely applied to the periosteal surface, as well as from the third and fourth sacral nerves of the spinal system So long as the cervix maintains its normal position with regard to the posterior pelvic wall so long there will be no tension upon these nerve filaments but immediately that position is altered by the rupture of the genito-sacral ligaments which keep the cervix in due apposition tension on these nerve fibres will commence and increase with every degree of departure from its normal proximity to the sacrum.

Again, the veins which return the blood from the uterus—the uterine veins—follow the course of the uterine arteries. Now it is well known that traction upon the uterus in a downward direction will so kink and narrow these arteries that section of the uterus may be made through its entire extent without loss of any appreciable amount of blood so long as that traction is kept up though the cut surfaces will bleed freely if the uterus is allowed to resume its normal position. The less resistant and much thinner vein wall will be still more easily affected by descent produced by any cause. As the blood current in them is delayed hyperæmia of the organ must necessarily ensue and the uterus become heavier still. Such increased weight leads to increased obstruction and a vicious circle is formed, escape from which is only possible by the restoration of the organ to its normal plane and its retention there.

From this point of view a survey of the various operations practised brings out still more plainly their inefficiency Amputation of the cervix, which I have omitted, although it may decrease the actual weight at the moment, can never reapproximate the lower part of the uterus to the sacrum and so relieve tension in the nerve fibres supplying that organ. And the same objection applies to any operation upon the mucous membrane of the vagina or upon the perineum. I believe that the words which I have quoted from Mr. Bowreman Jessett in the introduction of my thesis are absolutely true and that slowly but surely the weight of the heavy uterus above acting as a wedge will open up again the passage beneath, which has been temporarily narrowed, however ingeniously it may have been done, and it is evident that even immediately after operation the normal relation of the cervix to the sacrum has not been reproduced. The same precisely may be said of Alexander's Olshausen's, or any of the other operations which deal solely with the round ligaments Ventrofixation will certainly relieve the venous hyperæmia by taking off the narrowing strain upon the blood vessels of the uterus, but it cannot in any way replace the cervix in its normal relation with the sacrum and so restore the nerve filaments to their normal freedom from tension.

One last operation has been practised for the relief of this condition and surely we are justified in considering it the last effort of despair This operation was described by Professor Edebohls at the Manchester meeting of the British Medical Association in July 1902. When all else fails this operator removes the uterus, and with it the mucous membrane of the vagina down to the vulval edge. Then he of the isthmus uteri in the female, outwards and back wards on each side to blend with the tissue on front of the lower end of the sacrum and the back of the rectum. The two genital folds, two well marked peritoneal ridges *covering* these ligaments, become continuous with one another on the back of the isthmus uteri, forming the torus uterinus in the female." These bands are therefore true ligaments, and although small and covered by peritoneum in such a way that their actual character at first sight may escape, and has escaped, recognition, are far more important as to resisting and supporting power than mere peritoneum could by any possibility be. Before the cervix, and with it the uterus, can descend, still more before they can be everted, as we see them in procidentia, these musculo-fibrous bands the utero-sacral ligaments, must be *weakened relaxed, or torn* through.

Besides these true ligaments of the uterus, upon the integrity of which, I contend, the maintenance of its normal position depends, there is another and broader attachment of the uterus—that, namely, to the bladder, which at first sight would seem to have much to do with its retention at a proper level. But firm as this connexion is, its value is greatly discounted by the mobility of the bladder itself, an organ by no means firmly attached to its surroundings and the posterior wall of it, to which the uterus is connected; being a structure which is continually varying in its position as the viscus of which it is a part is filled or emptied. Everyone's experience of prolapse, and *still more of procidentia, is that* in such cases the bladder loses its own position and is dragged downwards by the descending uterus Indeed, the converse theorem might be far more safely held, that the bladder depends greatly for the maintenance of its normal position upon its attachment to the uterus and through it upon these ligaments than *vice versâ*. Such a theorem would obtain additional support from the fact that Professor Dixon and Professor Birmingham describe these sacro genital ligaments as existing also in the male In male subjects they are attached anteriorly to the base of the bladder and assist materially in its retention in its normal position.

The broad ligaments are usually considered to be amongst the more important structures which maintain the uterus at its normal level, but, I confess, I think without good reason. These ligaments—so called, since they contain no real ligamentous tissue—are composed entirely of two folds of peritoneum, inclosing between them some loose connective tissue, arteries, veins, lymphatics, and a portion of the ureter They have no true resistant power against descent of the organ which they inclose. Like all other portions of peritoneum they are capable of great extension by slow but persistent forces acting upon them, this is evident in all cases of procidentia. The uterus may be outside the pelvis, outside the vulva, it is still embraced by the broad ligaments, which are not torn through but simply stretched, and such stretching has evidently not met with any determined resistance from them They are supple, smooth, in no way altered in structure, but have simply yielded passively to the forces brought to bear upon them. We see exactly the same thing in the formation of the voluminous sac of a large scrotal hernia. This capability of easy yielding to persistent force is indeed well exemplified in the changes which occur in these very folds themselves during pregnancy and still more in that portion of them which covers the uterus itself The peritoneal covering of an unimpregnated uterus is small indeed compared with the large expanse which lies upon that uterus at full term, but which is precisely the same, and will return to almost its original size and shape when once parturition is over

It is evident that we cannot rely at all upon merely peritoneal attachments to prevent or to restrain prolapse, so that the value of the broad ligaments for this purpose is a negligible quantity There are certain other things, the importance of which has been very generally emphasised by authors, as being more or less subsidiary factors in this question Such are (1) the angle at wh[illegible]he ute[illegible]us lies with reference to the vagina, (2) the poten[illegible]ity of the vaginal canal, as opposed to the idea of an actu[illegible] space beneath the uterus, (3) the action of the levator ani, pelvi[illegible] fascia, and transversi perinei muscles in maintaining suc[illegible] potentiality and in converting an actual canal into a valv[illegible]ar slit in the tissues, and (4) a postulated balance betw[illegible]n intra abdominal pressure and the external atmospheric [illegible]ressure. Such a case as the following, however, counterpar[illegible]of which must be in the memory of all operators, demo[illegible]rates that all these subsidiary factors may be absent or non-effective, and yet so long as the true ligaments of the uterus are intact that organ will not descend

A married woman, aged 51 years, attended at the Ancoats Hospital in July, 1902, with the complaint that her uterus was coming down. She had had two children, the eldest of whom was 27 years old The labour had been a severe one, necessitating the use of forceps, and she attributed all her troubles to this confinement. The uterus commenced to come down, she said, as soon as she began to go about. On *examination the perineum was found to be entirely absent*, the sphincter ani was split and the vagina and rectum had a common opening which was divided about half an inch above the skin level by a narrow band, the combined edge of the rectal and vaginal mucous membranes There were marked rectocele and cystocele, but the finger passed up the vagina found the uterus in its normal anteverted position and at its normal elevation in the pelvis Thus, although all subsidiary factors had been non effective for 27 years and the patient had been engaged in a laborious occupation, necessitating much standing, the uterus itself had not prolapsed, its intrinsic ligaments being intact. Incidentally, and inasmuch as all these patients describe their condition in *the same way*, as a "falling of the womb," this case emphasises the necessity of careful differentiation for operative purposes between true uterine descent and mere prolapse of the vaginal walls, for the latter of which conditions the operation for reproduction *of the sacro-uterine* ligaments is not required or suitable

Returning to the true ligaments of the uterus, I think that a few moments consideration will show that of the two sets —the fundo-pubic and the sacro uterine—the integrity of the latter is of by far the greater importance. Their relative shortness, the position of their implantation below the main bulk of the uterus, their coordinate action with the vesical attachment in front, all render them more effective in maintaining the uterus in its normal position than the comparatively longer round ligaments which act upon the fundus And, indeed, instinctively as it were, in all measures short of operative interference practitioners have always acted upon these facts Where the perineum and its contained muscular fibres are intact, and often when they are not, pessaries have been used designed apparently with the one idea of replacing or shoring up these *sacro-uterine* ligaments. I do not refer to rings or inflatable ball pessaries which, indeed, are mere mechanical plugs, but to those pessaries which act upon a scientific basis—Hodge's, Thomas's, and their modifications. These all act *in this* way, although their action has been otherwise explained and justified They support weakened and relaxed sacro uterine ligaments and if these are not torn through the support and rest so obtained may, and indeed often do, *permit of* the latter regaining their normal length and tone and so the patient may be cured by the use of these appliances When these ligaments are torn the upper bar of the instrument to some extent replaces them In the first instance, after a certain time the pessary *may be* disused, in the second it will always require to be worn, and this I conceive to be the reason why some patients will apparently be cured by pessaries worn for a sufficient length *of time* whilst others can never dispense with *their presence* Of course the integrity or otherwise of the other ligaments and of the perineum is a large factor in any given case, but not, I contend, of the primary importance which belongs to the *sacro* uterine ligaments.

But if this is true of cases treated by measures short of operation, how is it, then, that when operative interference is undertaken, the importance of these posterior ligaments *is so entirely ignored*? Schultze himself, to whose description I have already referred, makes no such suggestion in his *résumé* of operations for prolapse. The reason I believe *is to* be found mainly in the conditions under which *operations have been evolved* When first surgeons attempted to remedy this defect it was not possible as it is now to avail ourselves of all the routes by which the uterus might be reached The sacro uterine ligaments are *deeply seated and difficult* of access. Moreover, in all the *old text*-books on anatomy, as we have seen, they are described as mere folds of peritoneum. Not only is mere peritoneum useless but *to* the pre-antiseptic surgeon the peritoneum was *forbidden ground* It was the one structure in the body of all others to be avoided Even in operating on herniæ, where it is now recognised as so all important that the condition of the constricted gut should be known, the peritoneal sac in *those days* was opened only or less from time to time. Actual procidentia occurred first 12 months previous to examination. Defecation and urination were normal, but reposition of the uterus was required before the latter act could be performed. Her actual state on admission was as follows. The perineum was very short, about half an inch. The sphincter ani was complete. The uterus was outside the vulva and was somewhat enlarged and heavy. The sound passed three and a half inches. The os pointed to the anus. The general condition of the patient was good. The urine was normal. She had worn Thomas's, ring, and pot pessaries. The two first did not remain *in situ*. The last was extremely uncomfortable and ineffective, some prolapse still occurring, probably however, this was merely vaginal. On August 21st, 1902, the operation as described above was performed. Some difficulty with the intestines was experienced, notwithstanding the extreme Trendelenburg position. They were therefore allowed to escape and were surrounded and covered by warm flat sponges whilst the utero-sacral ligatures were placed. The left suture could not be satisfactorily made to penetrate the periosteum owing to the trouble caused by the intestines and the frequently jerking character of the respiration, so that the parietal peritoneum only on this side was embraced by the suture. On the right side, however, the suture was properly placed. On searching for the round ligaments, these were found to be so attenuated that only by drawing the fundus backwards and so putting their peritoneal covering on the stretch could they be recognised. After uniting their intra pelvic extremities the intestines were replaced and the abdomen was closed. No rectocele or cystocele was evident on inspecting the vagina afterwards. Urine was passed naturally at 11 A.M. on the next morning. The bowels acted well on the third day. Some pain was complained of over the hypogastrium on the morning after the operation but this was relieved after a suppository of morphia and did not return. From first to last no pain was complained of in the sacral region. On Sept. 1st (ten days later) Tait's perineorrhaphy with interrupted buried sutures was performed, the wound being afterwards sealed by celloidin. The patient made a perfect recovery without incident and was discharged from the hospital on Sept. 19th.

CASE 2.—The patient was a married woman, aged 46 years. She had had two miscarriages, the first occurred eight months after marriage nine years previous to examination, the pregnancy being ten weeks in duration, and the second took place 16 months after marriage with a pregnancy of two months. She had had one living child six years since. The confinement lasted for 50 hours with rupture of the membranes 24 hours before the appearance of labour pains and it was terminated by forceps and chloroform. 19 months after confinement she first noticed the descent of the uterus which came down suddenly. In the following year, 1898, she was forced by pain to go to a women's hospital in Manchester, the uterus being then outside the vulva. The condition was treated by rest and pessaries of various kinds. Since that time she had consulted various medical men and had been treated by some operation in another hospital, five weeks after which she had a ring pessary placed in the vagina. This came away on the following morning. After this she wore a pot pessary with straps for 12 months. This gave her great discomfort and she said that the uterus came down by the side of it, she gave up using it in November, 1901. Then she wore a ring pessary for a while. Since April, 1902, there had been some bleeding which had dribbled from time to time but never very much. Her menstruation had always been regular as to time but the period now lasted for a week. Before marriage it lasted for three days. Her last period commenced 14 days since. Defecation was always regular until Christmas 1901, since then she had had pain about the umbilicus before the act. Her condition at the time of examination was as follows. She was a healthy-looking woman, of medium height and of sanguine complexion. The uterus lay between the thighs with the fundus looking towards the anus and the os looking upwards towards the pubes. The vaginal wall was entirely everted and dry being covered by scaly epithelium. The os contained a small fleshy polypus, the pedicle of which sprang from just within the cervix. This was destroyed with the Paquelin cautery under cocaine. The fingers could be made to meet above the fundus, inclosing nothing but vaginal wall and peritoneum. There was no trace of the sacro-uterine ligaments to be detected by palpation. The perineum was short and after reduction of the uterus there remained marked rectocele and cystocele. On August 25th, 1902, the operation described above was performed. When the uterus was drawn up by the traction ligatures to its full height its fundus projected one and a half inches beyond the level of the abdominal wall, showing the great relaxation of the vaginal walls. The Fallopian tubes were normal and the ovaries were slightly cystic. After the operation upon both sets of ligaments the abdomen was closed by triple suture and sealed. After operation there were still marked rectocele and cystocele. On the 26th urine was passed naturally. She vomited slightly after the anæsthetic. There was no pain over the sacrum or elsewhere. The abdomen was supple. The temperature was normal until 6 A.M. when it rose to 99 6° F, falling to normal by 10 A.M. the same day. The respirations ranged from 24 to 30 and the pulse from 80 to 84. On the 31st the period began. Sharp pain was present before for about an hour which was situated above the pubes. She lost more than for the last two or three years during which time it had been scanty and unsatisfactory, coming on for a few days, ceasing, and returning again. She thought that this period was much more natural and felt better after it than she had done since the uterus came down. The period lasted for five days. On Sept. 8th the abdominal wound was healed. Tait's perineorrhaphy with interrupted buried sutures was performed. The deeper tissues had so far retracted that the needle had to be carried close to the ascending pubic rami before sufficiently resistant material could be found for satisfactory reunion. Even when finished the space immediately in front of the sphincter did not seem to be sufficiently firm. The surface was sealed by celloidin. On the 9th urine was passed naturally at 4 A.M. On the 17th the abdominal sutures were removed. On Oct. 6th she returned home well and perfectly sound. There was some little delay after the last operation owing to the presence of pus in the tip of the vaginal flap and it was feared that one of the buried sutures might be infected, but douches with creolin cleared this up and no suture was extruded. The temperature throughout the whole stay in hospital never rose beyond 99 4°. The patient was shown at Stockport on Nov. 20th, 1902, and the result was confirmed by examination by three members of the Stockport Medical Society, one of whom was the president, and another the previous medical attendant who had been present at her confinement which he described.

Although the number of cases is but small they are perhaps sufficient to show not only the practicability of the operation but the good results to be expected from it. Its claim to be considered a rational attempt to attack the problem of prolapsus uteri in a scientific manner will rest upon the due consideration by operators of the anatomical conditions present in these cases and their appreciation or otherwise of the various arguments I have endeavoured to set forth.

Manchester.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NEPHRECTOMY BY LATERAL EXTRA PERITONEAL INCISION.

BY PETER PATERSON, M.B., C.M. GLASG., M.R.C.S. ENG.,
L.R.C.P. LOND.,
ASSISTANT SURGEON TO THE GLASGOW ROYAL INFIRMARY.

ON August 4th 1898, a man, aged 58 years, came under my care with a history of which the following is a summary. Nine weeks previously he observed that his urine was blood-stained and also that there was some difficulty in voiding it. This condition lasted three days and then disappeared, only to return, however, the following week. This sequence, the passing of blood stained urine for a few days followed by the passing of clear urine for an interval of a few days, continued till admission to hospital. During the last four weeks he had, in addition, pain in the hypogastric region at the point of the penis and down the left thigh as far as the knee. Two days before admission he had for the first time pain in the left lumbar region. When first seen all the above unites the bared connective tissue between the bladder and urethra on the one side and the rectum on the other by a series of purse string sutures, beginning at the peritoneal opening, pushing this up and placing another immediately beneath. Proceeding in this way until he reaches the skin, this also is united and a continuous perineum is thus produced, as in the male, from the anus to the urethra. He adds, very properly, that the result must be carefully explained to the patient before submitting her to this transformation.

It is I think, evident that none of the operations which I have described, and which comprise all those at present in use for the cure of procidentia or prolapsus uteri, can fairly be described as producing a return to the normal condition, but that they are, on the contrary, simply substitutions of one abnormal and deformed state for another The change may be, and doubtless often is, an improvement on the original, but it is not, and cannot be, a reproduction of the *status quo ante*

As I have endeavoured to show, the genito-sacral ligaments, though small, are all important in maintaining the normal position of the uterus, in cases of prolapse, and *a fortiori* in those of procidentia, they are relaxed, lengthened, and in many instances are torn through In the slighter cases the support of a properly fitting pessary by allowing rest and time for them to recover tone will be all that is required, but in the severer instances, where they are absolutely torn through, no amount of rest will bring about their reunion Torn muscular fibre retracts and atrophies from disuse, in the case of small muscles such as these a few months will suffice to render them practically indistinguishable from the connective tissue in which they lie Can anything be done to replace them, once more to afford stability to the postero inferior segment of the uterus in its normal position?

Here it is well again to emphasise the importance, if we are to restore the uterus to its normal position and condition, of its being free to move within certain limits If absolute fixation of the antero superior wall of the uterus is faulty, still more would absolute fixation of its postero-inferior segment be injudicious, since the normal descent of the cervix in parturition would be prevented and the escaping fœtal head would find itself opposed by the immoveable wall of the sacrum, the coccyx and the firm fibrous structures spreading from them both At the same time an attachment must be contrived which will be firm and permanent For a fixed point the aponeurotic structures covering the anterior surface of the sacrum supply a perfectly satisfactory and sufficiently broad area for choice. In choosing the particular point the ureter and rectum must be carefully avoided. Both lie over these structures and beneath the peritoneum. Both are easily recognisable. So also are the nerve strands which form elevated flattened ridges It is wise also to choose a point fairly free from vessels The main vessels—the common and internal iliac arteries and veins—are too far out for any uneasiness to be felt on their account. I have found that a point between the rectum on the inner side and the ureter on the outer is well adapted for the purpose. As to the height vertically on the surface of the sacrum, the manner of selecting this will be dealt with later It will vary with almost every case.

In old cases of procidentia, as I have already pointed out, it is useless to search for the remnants of the original ligaments They will have atrophied, and even if they could be found after a long and difficult dissection, the result of which would be needless damage to the tissues involved, they would be useless for reparative purposes Whilst this is especially true in such cases it is also true in minor cases of prolapse Bovée[3] however claims to have found and united the torn ends of these ligaments both from the vaginal and from the peritoneal aspect, Personally I believe that in every case this is mere waste of time and exposes the patient to needless risks Like Mr Bowreman Jessett I do not attempt a dissection which must be extremely difficult and is from the very conditions present foredoomed to failure, but seek to substitute something which will act in the same way, which is easily accessible, and which is sufficiently firm to be trustworthy.

Now in the upper extremity of the posterior fornix a sufficiently firm resistant material is available which, whilst firmly attached to the cervix, yet is of sufficient length between its most superior point and that blended with the latter to permit of normal freedom of movement. It is this which is utilised as the new sacro-uterine ligament. Its superior surface is covered with peritoneum. If this is denuded by the removal of a short narrow strip, its connective-tissue surface is bared for attachment to the parietal peritoneum behind Greig Smith long ago showed that the most permanent adhesion possible was one between peritoneum and bared connective tissue, but in order still further to insure stability the suture which unites the two is passed deeply into the fibro-muscular layer of the vaginal fornix without, however, penetrating its mucous coat This is done on both sides, one suture on each side, and the cervix is now slung to the anterior wall of the sacrum by the upper anterior wall of the posterior fornix You will note that no attempt is made to attach the posterior fornix to the posterior wall of the uterus, as in Mr Bowreman Jessett's operation

The technique of the operation as I have carried it out is briefly this The protrusion being reduced the patient is placed in the extreme Trendelenburg position and the abdominal wall is opened by a median incision As soon as the intestines have sunk away from the pelvis towards the diaphragm two threads are passed through the broad ligaments, one on either side of the uterus inclosing tube and round ligament, the ends of these threads are tied and by them as tractors the fundus of the uterus is drawn forwards A special sound is passed up the vagina by an assistant and made to press upwards the posterior fornix so as to render it prominent On either side a stout silk thread is passed vertically through the substance of the fornix, avoiding the mucous lining, so that each protruding end is half an inch distant from the other and the whole loop is from one half to three-quarters of an inch from the cervix. The fornix is now applied to the sacrum and a spot is chosen directly opposite, free from vessels and subjacent nerves and ureter and well outside the rectum, where the needle carrying this suture is entered deeply so as to embrace the periosteum covering the bone, it is brought out again half an inch directly above its point of entrance Before tying this suture a narrow strip of peritoneum is removed from that portion of the fornix which lies in its grip, so as to bare the connective tissue beneath This is repeated on the opposite side, the sutures are tied and their ends are cut short Sometimes the position of the rectum will only permit of single fixation This should then be more central in its position as regards the uterus and somewhat broader The new ligament or ligaments are now formed and the cervix hangs in its normal position from the sacrum by that portion of the vagina which lies between it and the sutures. The traction threads through the broad ligaments are now removed. As in all cases of procidentia the round ligaments have been also greatly lengthened, they are now shortened by Olshausen's method But it is important not to shorten them to their fullest extent, so as to permit of some play still being left, so that the uterus may rise with the filling of the bladder beneath as in the normal condition For this part of the work, Doyen's pubic retractor is very useful, giving as it does a clear view of these ligaments and of their points of exit from the pelvic cavity I have found it to be rather in the way in the earlier stage, so that I only introduce it after the new sacro uterine ligaments have been made After shortening the round ligaments it is removed and the abdomen is closed The position of the uterus and vagina is now as nearly as possible that which obtained before prolapse began, whilst the uterus itself is perfectly free to move within normal limits, perfectly free to develop in its entirety This manœuvre does not, of course, exclude or attempt to take the place of perineorrhaphy if this should be necessary, but any repairs of this kind I prefer to carry out at a later time, about 14 days afterwards if all goes well Of all the methods by which perineorrhaphy can be carried out Tait's appears to me to be the most rational, with certain modifications, but these are outside the scope of the present paper

I have now performed this operation upon ten patients, but as their history and results are so far almost identical and this paper is already so long I shall only give details of two

CASE 1 —The patient, a married woman, aged 30 years, had had two children, the eldest being six years old and the youngest four years old Her first confinement lasted for three days and was terminated by forceps She attributed her prolapse to a fall down three stairs with the child in her arms nine days afterwards. Since then she had felt it more through the lower wound into the pelvis. Two days later the edges of the lower wound became red and swollen. The stitches were taken out and fomentations were applied and the inflammatory trouble soon disappeared. The patient was fed with nutrient enemata, beef tea, and milk alternately for seven days, and then she was given in addition one drachm of meat juice by the mouth every two hours, two days later milk was given in gradually increasing quantities, until by the eleventh day she was taking three pints of milk in the 24 hours and one drachm of meat juice every two hours. On the fifteenth day she was taking fish. She left the hospital for the convalescent home five weeks from the date of admission

---

[3] American Journal of Obstetrics July 1902

I saw her four months later when she expressed herself as being quite well. There was no abdominal tenderness or pain after food and she could take any kind of food, she said that she was more comfortable than she had been for the last three years. I saw her several times subsequently as she complained of pain in the region of the inguinal scar, and here a ventral hernia was developing Pressure with a pad was tried but gave no relief. As the hernia not only gave rise to much discomfort but was also a source of great anxiety and was rapidly increasing in size I recommended an operation for its radical cure. On Nov 15th, 1902, the scar and hernial sac were excised and the various layers of the abdominal wall were sutured separately The coils of small intestine which presented in the wound during the operation were smooth, shiny, quite free from adhesions, and bore no trace of the process through which they passed eight months before. On Feb. 6th, 1903, I found that there was no bulging in the site of the old ventral hernia

Queen Anne-street, W

A CASE OF EMPHYSEMA IN VIOLENT LABOUR.

By John Braithwaite, M.D Durh,

Physician to the Devonshire Hospital and Buxton Bath Charity

The patient, who was a primipara aged 24 years and of small stature, began to have labour pains about 3 P.M. on Feb. 14th, 1903. From the first the pains were frequent and violent. The membranes ruptured about 11 P.M. About midnight her mother noticed that her face and neck had begun to swell. I saw her about 4 A.M. on the 15th when pains with very violent expulsive efforts were occurring about every three minutes. The pulse rate was 120 The fœtal head was in the first position and half an inch from the perineum. On placing my hand over the abdomen I found that the uterus was not always contracting when the patient was 'bearing down." There was well marked emphysema over the base of the nose, both sides of the face, the front and both sides of the neck up to the mastoid processes, and over the whole of the front of the chest as far as the nipples. She complained of her neck being painful on movement and said that the skin crackled like brown paper There was also hæmorrhage into the inner half of both conjunctivæ. A little chloroform stopped the expulsive efforts and lengthened the intervals between the proper pains. Labour ended about 6.30 A.M. without any further trouble. Convalescence was uninterrupted. On the 16th the emphysema had disappeared from the base of the nose. On the 17th it had almost left the cheeks, but whilst straining at stool she could feel the sides of her neck being puffed out. On the 19th the face and upper half of the neck were quite clear and on the 23rd I could only find a few isolated patches on the chest By the 28th the emphysema was all gone.

Buxton.

A CASE OF FLOATING KIDNEY IN AN INFANT

By Rees Phillips M B Lond,

House Surgeon to the Hospital for Women Brighton

Floating kidney and moveable kidney appear from the literature of the subject to be very rare in infancy Morris states that a floating kidney with a mesonephron is 'excessively rare." I have therefore thought that the following case might be worth recording in this connexion

The patient was a male child, born on Feb. 4th, 1903, whom I was called to see a few days after birth on account of an attack of greenish vomiting attended by collapse. When seen by me the child had recovered from the attack and looked apparently healthy and well developed Examination of the abdomen revealed a very lax and atonic condition of the walls and there appeared to be a small oval tumour causing a prominence of the abdominal wall just below the ribs on the left side. Palpation showed that this tumour was the left kidney "floating" forwards. It glided about readily within the abdomen and could be displaced forwards so as to come in contact with the abdominal wall just to the left of the umbilicus. The right kidney was also "moveable," but not 'floating" Its movement was chiefly in a vertical direction and the anterior and posterior walls of the abdomen could be compressed together above its upper extremity and the kidney thus held down. Since then the patient has had about half a dozen similar attacks of green vomiting and the mother states that he has had three attacks of "convulsions" with foaming at the mouth The child is very constipated. Whether the symptoms are dependent on the abnormal mobility of the kidneys or are merely coincident I cannot say The symptoms do not appear to be influenced by the position of the child As the floating kidney has existed from birth this must be a case in which a mesonephron exists

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

A Case of Multiple Myeloma with Bence Jones Proteid in the Urine

A meeting of this society was held on March 10th, Mr **Alfred Willett**, the President, being in the chair

Dr F **Parkes Weber** read an account of a case of Multiple Myeloma with Bence-Jones Proteid in the Urine. He said that the patient, a rather fat man, aged 50 years, complained of rheumatoid symptoms commencing about the end of the year 1899 About February, 1900, he began to suffer from pains in the loins and stiffness in the small joints of his hands. Soon afterwards the upper part of his back began to bend so that he always had a stooping attitude. Previously to this illness the patient had been strong but as a young man had had gonorrhœa and a chancre on the penis. One of his sisters suffered from diabetes mellitus. The urine of the patient was found to contain the Bence-Jones proteid. The daily amount of the urine was about 2000 cubic centimetres and it contained about seven per mille of the proteid as measured by Esbach's albuminimeter By a more exact method (precipitation with alcohol, drying and weighing) Dr R. Hutchison found that about 15 grammes of the proteid were excreted daily The reactions of the proteid were the typical ones described by Dr Bence-Jones, Dr Kühne, and Dr T R. Bradshaw For some time the patient's condition remained fairly stationary and at first by the use of local hot baths massage, &c., the power of bending his fingers was improved. Afterwards, however, the general weakness, cachexia, and anæmia greatly progressed and gummatous disease of the tongue and on one rib made its appearance. Examination of the patient's blood showed slight leucocytosis. In January 1901, it was found to contain about 23 per cent of the normal hæmoglobin In the cubic millimetre there were 2 980,000 red cells and 11,000 white cells (25 6 per cent. lymphocytes, 3 per cent. large mononuclear 70 3 per cent. polymorphonuclear and 1 per cent eosinophile) No myelocytes or atypical cells were detected amongst the leucocytes. On Jan 25th, 1902, the patient died after copious hæmorrhage from the intestines, which post-mortem examination showed to be due to chronic ulceration of the duodenum. The Bence-Jones albumosuria persisted to the last. At the necropsy the bone marrow of all the bones examined was found to be more or less affected by a diffuse sarcoma like growth of rounded or polyhedral mononuclear cells, a form of multiple myeloma" or 'myelomatosis." A report on the microscopic characters of the new growth by Professor R. Muir was quoted. The presence in the tumour of cells containing granules and globules of various sizes constituted a striking histological feature in the present case The new growth was confined to the bones and formed no localised tumours projecting from the bones, such as had been noted in some cases of multiple myeloma. In fact, neither by direct symptoms were present. The urine, which was of average quantity, was dark red, with an acid reaction and a specific gravity of 1024. Microscopically a large number of red blood corpuscles with a few epithelial cells were evident. Tube casts could not be recognised Physical examination revealed the presence of a distinct enlargement of the left kidney, which was tender on pressure. All the other viscera appeared healthy On the 13th an incision was made on the left side extending from the tenth costal cartilage to a point an inch internal to the anterior superior iliac spine All the structures down to, but excluding the peritoneum were divided in this line. The serous membrane was then reflected from the abdominal walls till the whole of the anterior surface of the kidney and a considerable part of the renal vessels were exposed. The gland was then removed by separating it from the surrounding tissues and tying the vessels and ureter between double ligatures A small incision was next made in the loin by cutting down on the point of a pair of dressing forceps introduced through the anterior opening Through the lumbar wound the cavity was loosely packed with sterilised gauze, whilst the anterior incision was stitched in layers with catgut. Two days later the packing was removed and, as there was only a little serous stain in the dressings, just sufficient gauze was introduced to keep the posterior wound open After other two days the packing was dispensed with entirely The patient's progress after the operation was satisfactory for a month, the wounds healed and the quantity of urine and urea averaged 50 ounces and 400 grains respectively per day A trace of albumin, however, was still present The patient now began to show signs of mental confusion and this condition gradually became worse till by the end of September he was unable to answer any question intelligently In the beginning of October dermatitis affecting the whole surface of the body appeared. This gradually improved under treatment so that by the end of the month the skin was practically well Three weeks later the patient's mental condition had quite cleared up and he left the hospital with, however, the albuminuria still present, though not so marked During the whole of this period the urine was normal in quantity and contained on an average 420 grains of urea in the 24 hours Tube casts were never observed The patient was seen every few weeks after leaving hospital and his urine was examined, but it was not till eight months after the nephrectomy that the albumin had quite disappeared.

He was last seen four weeks ago—i.e., four and a half years after the operation—when he appeared to be well in every respect The anterior incision was represented by a linear cicatrix which showed no tendency to stretch. There was no apparent weakness of the abdominal walls notwithstanding the fact that he was regularly employed at his work as an engine fitter Sensation between the middle line and the cicatrix was only very slightly blunted.

The kidney on removal was found to be enlarged in its lowest third to double the normal size whilst the remainder was regular in size and shape On cutting the organ open it was evident that the enlargement was due to a tumour into which blood had been extravasated Microscopic examination demonstrated that the neoplasm was a carcinoma undergoing colloid degeneration

The advantages of removal of the kidney by this method far outweigh its disadvantages The organ is easily accessible, there is no stretching of, or tension on, the vessels, large tumours can be removed through the wound, whilst the ureter if necessary, can be exposed almost down to the bladder The intestines do not come into the field of operation, the blood supply of the colon is not interfered with, and the shock consequent on opening the abdominal cavity is obviated, whilst the wound is not any deeper than in the transperitoneal method In the case of stone the viscus can be thoroughly examined between the fingers. In septic conditions the peritoneal cavity is not infected. Adhesions, both anteriorly and posteriorly, are easily reached, whilst in those cases where the peritoneum is so adherent to the kidney that it cannot be stripped off and the abdominal cavity has to be opened this part of the operation is much easier than by the lumbar incision and is not any more difficult than by the abdominal route. The disadvantages are (1) that the opposite kidney cannot be examined through the wound and (2) that a risk of ventral hernia is incurred, but in the case of wounds taking an aseptic course the latter objection is more theoretical than real, as the above instance shows.

Glasgow

EXCISION OF A PERFORATING GASTRIC ULCER.

BY ARTHUR EVANS, M S. LOND, F R C S ENG

ASSISTANT SURGEON TO THE WESTMINSTER HOSPITAL SURGEON IN CHARGE OF OUT PATIENTS SEAMEN'S HOSPITAL SOCIETY ROYAL ALBERT DOCK.

A WOMAN, aged 36 years, was admitted into the Westminster Hospital late on the evening of April 25th, 1902, suffering from acute pain in the abdomen. She was brought to the hospital in a hansom cab, but walked into the surgery Her condition on admission was as follows. She lay in bed with her knees slightly flexed, her face was not anxious, nor were her eyes sunken, her tongue was moist and clean, her pulse was 120 per minute, regular and easily compressible, and her temperature was 100 2° F When I saw her, half an hour after admission, her temperature had risen to 100 8° and her abdomen was rigid, slightly retracted, and tender all over, the tenderness being most marked over the region of the stomach The previous history was to the effect that she had been an in patient in the Middlesex Hospital four and a half months previously with a four months' history of pain increased by food and relieved by vomiting She was there found to have marked tenderness over the whole of the left abdomen, most marked at a spot two inches above, and to the left of, the umbilicus Nothing else was found In eight days her pain had disappeared and in three and a half weeks she was discharged from the hospital The history of the present illness was as follows For the last three days the patient had had a return of the old pains after food On April 25th, at 3 P M she was suddenly seized with severe abdominal pain and vomited once, the vomit consisted of food only, there being no blood in it. The pain was exceedingly severe from the very beginning, causing her to keep her knees drawn up, it was felt all over the abdomen but was most marked in the left hypochondriac and epigastric regions

The diagnosis of perforation of a gastric ulcer having been made the abdomen was opened by a four inch incision in the mid line between the umbilicus and the ensiform cartilage. On opening the peritoneum some fluid escaped which was whitish, opaque, and greasy On passing the hand over the front of the stomach it was found to be adherent to the anterior abdominal wall At this site the stomach wall was very much thickened so much so that malignant disease was feared Cutting through the adhesion, which was about a quarter of an inch thick, the thickened portion of the stomach was drawn out of the abdominal cavity and the peritoneal cavity was shut off by gauze pads In the centre of this thickened area and by the side of the adhesion was a round hole of the size of the end of an ordinary black lead pencil, through this, stomach contents were passing, amongst which pieces of cauliflower could be recognised In order to determine the pathological nature of the mass in the stomach wall an incision was made through it into the stomach, the incision crossing the perforation, when it was seen that the mucous membrane was free from malignant disease and the stomach wall, although here an inch in thickness appeared to owe its altered condition entirely to inflammatory processes. (Subsequent microscopic examination confirmed this.) To put an end to the constant leakage of stomach contents through the hole the interior of the stomach was lightly wiped out with sponges. The greatly thickened tissues surrounding the perforation did not permit of the invagination of that portion of the stomach wall, so that area, measuring about two and a half by one and a half inches, was excised. The mucous membrane of the rest of the stomach was normal, and there was no obstruction to the finger passing into the pylorus The mucous membrane was sewn up with a continuous silk suture and the other coats were brought together with one row of Lembert's sutures, the stitches passing well beyond the edges of the wound and an occasional one being afterwards inserted here and there along the line of suture as seemed advisable. An incision was made in the right inguinal region and through this and the upper wound the peritoneal cavity was mopped out with sponges and then thoroughly flushed with sterilised water The whole of the cavity was again as far as possible sponged over and the wounds were sewn up, an iodoform gauze plug being placed in contact with the wound in the stomach and brought out at the lower end of the upper wound and a large-sized curved glass tube was passed difficulty might be experienced in distinguishing appendicular abscess within the pelvis from inflammatory and suppurative affections originating in the genital organs. A case of pyosalpinx was quoted in which the pain and tenderness were referred to the right iliac fossa and a case of suppurative ovarian cyst was related which had for three years given rise to attacks which were believed by several good observers to be due to appendicitis. In conclusion, a case of appendicular abscess deep in the pelvis was referred to which was opened by an incision resembling that employed for external prostatectomy through the perineum between the urethra and rectum.—The PRESIDENT referred to cases which he had seen of tuberculous disease in the region of the cæcum and appendix which resembled appendicitis very closely. He had also met with three cases of ovarian tumour with a twisted pedicle which had given rise to the greatest difficulty in diagnosis; in two of these the tumour was found lying in the iliac fossa. A case of perforated duodenal ulcer in a girl, aged 20 years, had also given rise to symptoms of appendicitis. An abscess was opened in front and a fæcal fistula resulted. Subsequently an empyema formed which was drained, food passing through the opening. The patient ultimately recovered.—Mr ALBAN H. G. DORAN had frequently seen ovarian tumours with twisted pedicles mistaken for appendicitis. He referred to a case of tuberculous vermiform appendix occurring in a patient aged 24 years, which appeared to be part of a localised tuberculous ascites. He also referred to a complicated case of salpingitis which appeared to have spread from the opposite side and which was associated with appendicitis. He was satisfied that salpingitis might spread from one tube to the other.—Dr F. DE HAVILLAND HALL related a case which was regarded as an incarcerated epiplocele but in which it was found that the appendix had passed down the femoral ring. Cases of hysterical patients often presented much difficulty in diagnosis.—Dr H. A. CALEY thought that when there was much and long-continued pain lesions of the colon rather than of the appendix should be suspected and he referred to a case of a middle aged man who had suffered from continuous pain for four years, the case having been regarded as appendicitis and the appendix having been removed without relief.

Dr A. H. N. LEWERS communicated a case of Abdominal Hysterectomy for a Retro-peritoneal Cervical Fibroid weighing 13½ pounds. The patient was a single woman, aged 42 years, who had noticed a swelling of the abdomen for three or four years. The tumour was removed and the patient made a good recovery, leaving the London Hospital on July 22nd, 1902. Reference was made to previously recorded cases[1] and stress was laid on the fact that such retro-peritoneal cervical fibroids formed a class by themselves. The operation for their removal was a very extensive one. This was the sixth case which Dr Lewers had operated upon.—Mr ALBAN DORAN said that he could not regard merely the size of the tumour as a cause of shock. Dr Lewers's case was a true cervical fibroid, but so-called retro-peritoneal cervical fibroids were often not of uterine origin, being connected with the broad ligament.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on March 5th, Dr W. Winslow Hall, the President, being in the chair.—Mr J. P. Lockhart Mummery read a paper on the Value of Arthrotomy in the Treatment of certain Joint Lesions. He pointed out that many cases of what might be called subacute septic joint lesions followed or occurred contemporaneously with infections such as influenza, scarlet fever, measles, or pneumonia. Other cases occurred after some septic lesion such as a whitlow or in oral sepsis, and the organism of the lesion had been demonstrated in the fluid contained in the joint. Certain cases known as chronic rheumatism or rheumatoid arthritis, might in reality be pyæmic in origin and comparable with gonorrhœal arthritis. Mr Mummery then dealt with two types of septic arthritis following infection of the blood—the acute and the subacute, sometimes called 'pyæmic arthritis,' but not part of a general pyæmia. The primary focus from which the blood was infected was often insignificant. Acute septic arthritis was generally the result of direct infection from a wound and rarely proceeded from the blood except as part of a general pyæmia. In one patient, however, aged 21 years who was out of health a slight abrasion of the finger caused a pustule. Five days later he felt a sudden pain in the left ankle. Four days later he was admitted to a hospital, very ill, with a temperature of 102° F. and the left ankle much swollen and inflamed and evidently containing pus. The finger had nearly healed. Incisions were made into the ankle which was treated with a continuous water bath. The incisions had to be opened again a week later and ultimately septicæmia rendered it necessary to amputate. After this the patient recovered. There were no history of traumatism, no previous joint disease, and no general pyæmia. The infection seemed to come from the finger and earlier opening of the joint would probably have saved the limb. Subacute septic arthritis might follow sepsis after pregnancy or the acute fevers or gonorrhœa. Treated by rest and lotions these cases showed frequent formation of adhesions or recurring attacks of synovitis, whereas opening the joint and washing it out gave excellent results. The joint lesions were often mistaken for acute rheumatism but the condition did not react to salicylates. In gonorrhœal arthritis there was a marked tendency to the formation of adhesions and recovery was very slow, but with opening and washing out the joints, especially if done early, the disease usually rapidly subsided. Mr Mummery alluded also to the use of arthrotomy by Dr John O'Conor of Buenos Ayres in cases of acute rheumatism. It was claimed that this treatment lessened the duration of the disease and the liability to cardiac lesions. Dr O'Conor believed that the joints formed the infected foci from which the heart was affected. In England, where rheumatic fever seemed to react to the use of salicylates, it was difficult to believe that arthrotomy was needed. Mr Mummery here described the practical details of arthrotomy at some length. He regarded the operation as simple and practically free from risk, the open method being infinitely superior to aspiration. Before closing the wound it was important that all bleeding should be stopped.—Mr J. H. D. Phelps said that having worked for the last three years with Dr O'Conor he was able to speak very favourably of arthrotomy and irrigation in septic and gonorrhœal arthritis. As regarded the treatment of acute rheumatism by arthrotomy doubt had been thrown on the nature of Dr O'Conor's cases but those which Mr Phelps saw presented all the clinical features of the disease. Bacteriological observation had unfortunately not been carried out.—Dr Sidney P. Phillips said that septic joints were very rare as a sequel of the infectious diseases.—Dr John F. H. Broadbent and Dr S. Vere Pearson also took part in the discussion.

PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.—A meeting of this society was held on Feb. 25th. The annual report was read and adopted. The office bearers of the previous year were re-elected for another year.—Mr Harvey showed some microscopic sections from (1) a case of Hæmorrhage into a Suprarenal Capsule, and (2) a case of Congenital Multiple Sarcomata of the Skin (the full details of this rare case were given by Mr G. Pernet before the Pathological Society of London in April 1902).—Mr Percy Rose showed a naked-eye specimen of a Pancreas containing numerous Calculi.—Dr T. D. Lister read a paper on the Principles of Infant Feeding. He pointed out that all the divergences of medical opinion began from what was the common starting point of all practical workers—viz., that pure good cow's milk supplied the only generally applicable substitute for natural feeding. He condemned the encouragement of artificial feeding in the case of the healthy children of mothers able to feed them. After recapitulating the differences between cow's milk and human milk he said that the elaboration of percentage feeding was justified chiefly on theoretical grounds and contended that the essential differences between cows' and human milk prevented the attainment of a humanised milk in the literal sense. After referring to the proportion of whey proteid and curd proteid in the respective milks suggestions were made for the home preparation of modified milks based on the methods of Professor Rotch and Dr White and Dr Ladd. He drew attention to the value of a certified milk system, as recently referred to by Dr Coutts and thought that more coöperation with the milk trade would afford a useful field for some of the activities of local medical societies. For the less intelligent and also the poorer classes, where a little milk had to go a long way, dilution with cereals, or even with water simply, was a valuable method and one often adopted for routine practice in hospital extension nor by metastasis were any other parts of the body involved. Dr Hutchison and Dr J J R. Macleod made a careful chemical investigation of the bones, blood, and organs, but failed to find in any of these tissues or organs a body giving exactly the same reactions as those of the Bence Jones proteid in the urine From the vertebræ and ends of the femur, however, they obtained a proteid giving very similar reactions, differing somewhat in the temperature at which it coagulated and in not being re dissolved on boiling Moreover, no similar proteid could be obtained from normal red bone marrow They argue that in the present case the bone marrow was probably *the seat of production of the* proteid excreted in the urine and that this proteid was not a non assimilated digestive proteid as suggested by Magnus-Levy Though the case was complicated with syphilitic gummata, chronic ulceration of the duodenum, and a generalised rheumatoid affection of the joints it was a typical one of multiple myeloma with Bence-Jones proteid in the urine, the ' myelopathic albumosuria " of Dr Bradshaw, also called in Italy ' Kahler's disease " When the diagnosis was first made it was probably the second case of the kind recognised *during life* in England, the first one being that recorded by Dr Bradshaw in 1898 In the latter part of the paper various questions regarding multiple myeloma with, and multiple myeloma without, 'Bence Jones albumosuria " were discussed and a summary was appended of all the hitherto recorded cases in which Bence Jones proteid had been detected in the urine, including certain cases in which no bone disease was discovered and certain other cases in which the reactions of the proteid in the urine were not quite characteristic. Multiple myeloma was regarded as a convenient term to include various forms of myelogenic new growth Two types at least were to be distinguished (1) a growth like the present, in which the bone marrow only was involved, and (2) a growth in which nearly all the cells resembled small or large lymphocytes and in which lymphatic glands as well as bone marrow were affected. Taking all the data that could be obtained into consideration Dr Weber stated the following conclusions (1) that Bence-Jones albumosuria was always the result of disease of the bone marrow, (2) that it was due to an abnormal metabolic or degenerative process in the myelocytes or in the tumour cells derived from the myelocytes or their predecessors, (3) that the reason why it was generally associated with myelogenic tumour formation was that the tumour cells derived from bone-marrow cells, however much they might morphologically resemble true bone-marrow cells, were more prone to abnormality than real myelocytes, and (4) that non myelogenic tumour cells were not affected in the same way and therefore metastatic tumours in the bone marrow did not give rise to Bence Jones albumosuria like myelogenic tumours

---

[1] Transactions of the Medical Society of London, vol. xxiv., p. 106.

Dr BRADSHAW (Liverpool) said that when five years ago he first brought a case of myelopathic albumosuria to the notice of the society not more than six cases had been described and that at the present time no less than 32 cases had been recorded. He considered that myelopathic albumosuria should be recognised as a definite disease, distinct on the one hand from osteomalacia and on the other from multiple tumours in the marrow unattended by changes in the urine He referred to a case of the disease at present under the care of Dr J Barr, in which sudden paraplegia and cystitis followed a feeling that "something had given way' in the back. He next dealt with the question whether the proteid was an albumose or an albumin He said that in its chemical behaviour it seemed to be intermediate between a native albumin and proto-albumose The coagulum by heat was much more soluble than that obtained from native albumin and had been said not to be a true heat coagulum. The nitric acid reaction was identical with that of proto albumose, and, on the other hand, it was not dialysable The term "albumose" was applied by physiological chemists to bodies which differed considerably from one another in their chemical reaction Thus one member of the group, hetero-albumose was insoluble in distilled water, proto albumoses were coagulated by nitric acid and deutero albumoses were not coagulated by nitric acid The essential idea of an albumose was a proteid derived from albumin but with a smaller molecular weight and of less complexity than the latter Now all the albumins commonly met with contained a hetero-albumose group or radicle and yielded hetero-albumose and other albumoses when digested, and it had been shown by Magnus Levy that the Bence Jones proteid did not contain the hetero-albumose and therefore was probably an albumose He considered that it was probable that the new growth in the bones was the seat of the formation of the albumose. He pointed out that the disease more frequently affected males than females

Dr HUTCHISON said that it was of importance to determine where the proteid passed in the urine was produced He had examined all the organs, but had failed to find a proteid similar to that passed in the urine. A proteid was found in the portion of the medulla replaced by the myeloid growth, but it was not exactly of the same nature as that which was found in the urine. The view that it arose *from the cells* of the growth was probably correct, though it was difficult to see how the destruction of these cells could account for the quantity of proteid passed in the urine

Dr MACLEOD said with regard to the exact chemical nature of Bence-Jones albumose that its chemical reactions would indicate that it belonged to the native proteid group rather than to the proteoses. The biuret reaction was of a distinct violet colour, not a rose pink, which was characteristic of the proteoses From its other reactions no definite opinion could be deduced. To decide whether the albumose proteid was derived from the gastro-intestinal tract or not it would be necessary to restrict the proteids of the diet to a greater extent than had been done in Dr Weber's case By its chemical reactions its chemical nature could not be determined, but this in any future case might easily be done by injecting it into the blood of an animal and finding if a specific precipitin was developed.

Dr W LEE DICKINSON said that the occurrence of Bence Jones albumosuria was characteristic of myeloma of the bones and did not occur in cases of osteomalacia, lymph adenoma of the marrow, or Hodgkin's disease He referred to the excess of lime which was frequently found in the urine of diabetic patients and asked if any such excess had been found in this case

Dr HUTCHISON said that the lime had not been estimated, but there was a large excess of phosphates.

Dr WEBER replied.

MEDICAL SOCIETY OF LONDON

Conditions simulating Appendicitis with Cases of Appendicular Abscess in Unusual Positions —A Case of Abdominal Hystereotomy for Retro peritoneal Cervical Fibroid

A MEETING of this society was held on March 9th, Mr A PEARCE GOULD, the President, being in the chair

Mr FREDERIC S EVE read a paper entitled "Some Conditions simulating Appendicitis with cases of Appendicular Abscess in Unusual Positions." Five cases of tuberculosis of the cæcum were related the symptoms of which closely simulated appendicitis All gave a history of recurrent attacks of pain, sometimes commencing suddenly One patient was supposed for years to have suffered from gastric ulcer the pain being referred to the epigastrium In nearly all the cases constipation existed but vomiting was not marked except in one instance The chief point in which they differed from appendicitis was in the slight character of the local tenderness A swelling of firm consistence due to a thickened, indurated, and contracted cæcum was observed in all The appendix was only found once and was not tuberculous In one case observed by Mr Eve in 1901 there was evidence of chronic obstruction and a short-circuiting operation was performed with good result. The condition had been mistaken in one recorded case for carcinoma, from which, however, it was distinguishable clinically by the absence of leucocytosis Allusion was made to the difficulties in diagnosis in some instances between appendicitis and affections of the gall bladder, kidney, and intestine, such as carcinoma, colitis and obstruction by a band in the right iliac fossa cases being quoted in illustration In appendicitis the localisation of the pain and the position of the abscess were subject to great variations owing to modifications in the length and position of the appendix itself and vagaries in the position of the cæcum and other abdominal organs In one case the pain was referred to the right loin owing to the tip of the appendix being attached beneath the liver and in another the pain was always localised in the left flank. Cases of appendicular abscess beneath the liver and about the umbilicus (owing to non descent of the cæcum or unusual length of the appendix) were related Great of the food supplied. General failure of nutrition, however, may, and in no inconsiderable proportion of cases certainly does, depend on defective assimilation and dissimilation of the part of the tissues generally quite independently of functional disabilities of primary digestion This distinction we cannot help thinking has not been made sufficiently plain in those chapters of the present volume which deal with the subjects of nutrition and malnutrition. If we examine, for instance, the chapter on Marasmus or Athrepsia, as it is now generally called, it is to be observed that this condition of simple wasting is described as an extreme form of malnutrition occurring in infancy and independent, as far as is known, of constitutional or local organic disease, in fact, that it is a vice of nutrition only This definition though little calculated to meet with the approval of those who attribute this disease to atrophy of the gastric and intestinal glands, would be quite in harmony with post-mortem evidence, as well as with the more recent views of Bouchard and his school, if the term 'vice of nutrition" were allowed to apply to the vital activities of all the tissues of the body equally with those of the intestinal tract proper, which, so far as we understand it, is not Dr Holt's meaning

Although in the preface the author informs his readers that his purpose has not been to ' deal with surgical topics more than in their medical aspects,' we notice that in the chapter on Adenoid Growths considerable space is devoted to their surgical treatment. In addition to our objection on general principles to physicians usurping surgeons' prerogatives we consider that in this instance the value of Dr Holt's book is not enhanced by his account of this particular surgical operation—indeed, we imagine that most surgeons in this country would hardly admit that "the majority of the growths encountered in ordinary practice can be removed with one sweep of the curette" There is, indeed, a danger by such a method of procedure of the periosteum being stripped from the posterior wall of the pharynx if too much energy is displayed in the use of the curette. Such an accident has, within our own knowledge, occurred on more than one occasion and might with advantage have been included among the dangers of the operation enumerated by the author

With regard to the subject matter generally of the present volume it must be admitted that, with very few exceptions, it has been brought remarkably well up to date. And in this connexion we notice that although the congenital condition of pyloric stenosis has been most adequately described, another congenital condition of probably equal importance—namely, achondroplasia—is entirely omitted both under this name and under its numerous synonyms. Owing to the similarities of this condition with that of fœtal or congenital rachitis, to the mistakes in diagnosis which are likely to occur when this somewhat rare disease is met with, and to the interest which attaches to the disease, it is to be regretted that this omission has been made.

As a work of reference on the diseases of children we regard this recent edition of Dr Holt's book as even more complete and trustworthy than the last edition of Professor Baginsky's classical work on the same subject which was recently reviewed in THE LANCET[1] Moreover, it is more readable, more practical, and more up-to-date. In fact, in our opinion, there is no work on the subject of the diseases of infancy which is comparable with the volume under review and with the exception of Dr Rotch's "Pediatrics," no book with which we are acquainted contains anything like such full, systematic, and accurate directions for the feeding of infants, either in health or in disease.

A Text book of Palæontology By KARL VON ZITTEL. Translated and edited by CHARLES EASTMAN, Ph.D Vol. II. With 373 figures in the text. London Macmillan and Co Pp. 283. Price 10s. net.

THIS the second volume of the translation of Professor Zittel's shorter work upon Palæontology deals with the lower vertebrates from fishes to birds, the mammalia being reserved for a third and final volume. It is not merely a translation of the German original but is to be looked upon as a partly new work since addition to, and some slight alterations in the arrangement of, the facts detailed by Professor Zittel have been made by various gentlemen in America and in this country at the request of the editor

Palæontology is making such rapid strides at present that the antiquity of a text-book on the subject is apt to be measured more correctly by months than by years It therefore behoves an editor of a responsible and authoritative work like the present to keep a very keen and constant eye upon current zoological literature. This appears to have been the attitude of Professor Eastman and his colleagues, with the result that the student of the general facts of palæontology, so far as they are embraced in this volume, can follow the instruction given with confidence. That instruction is, however, dealt out in a highly concentrated state, so much so perhaps as to be not easily assimilable by the novice. The author and his several editors have been at pains to fit in every corner with information and have thus produced a handbook which is just a little bit suggestive of a dictionary The desire of making the reader acquainted simply with names in default of other facts has been pressed a little too far Thus, of the Stegocephalan genus Macromerion all that is said is 'Imperfectly known." In such cases the elementary student might perhaps have been better left in temporary darkness and the space thus saved might have been devoted to a less pemmican like description of forms not "imperfectly known." For an avowedly elementary text-book the section devoted to Fishes appears to us to be in comparison inordinately long, and here the practice of the simple mention of names and localities is carried to an excess not approached elsewhere in the manual. On the other hand, the minute differences which distinguish allied genera or even families of bony fishes are set forth at times with a prolixity which is surely out of place in a book which does not pretend to exhaustive treatment.

From minor faults Professor Zittel's handbook is singularly free, but we have noticed one or two For instance, in treating of the Ganoid fishes the family Aspidorhynchidæ is printed in "clarendon" type and is followed by "Woodward' in 'small pica" type. On the very next and, indeed, opposite page another family of the same group of fishes—viz., Lepidosteidæ—is distinguished by the same clarendon type, but the name of that family is in this case followed by 'Bony-pikes" in small pica—a state of affairs which leaves us in doubt as to whether "Woodward" is the popular name of a group of fishes or whether "Bony-pikes' is the name of some eminent palæontologist. Again, the name of a family of ancient and primitive lizard like beasts is given as ' Proterosauridæ.' We well remember that excellent and eminent surgeon and palæontologist, the late Mr J W Hulke, correcting a friend in thus pronouncing a name which should be written and pronounced "Protorosaurus" The name, in fact is not compounded out of an impossible and non-existent comparative of the Greek word for first, but is derived from two words meaning, of course, "first hour"—the lizard of the prime, in fact. But after all these are trifling blemishes and do not detract from the usefulness of the volume which will be a lasting testimony to the peculiar work. Commercial sterilisation was not to be depended upon, for it sometimes meant making a market for milk already undergoing decomposition. In regard to the feeding of children of the well to do and the use of predigested milk foods, he thought that it was wiser to use partially or completely predigested foods than to carry dilution to what was often almost starvation point, reducing the degree of predigestion as nutrition improved Finally, Dr Lister insisted that the striking feature of the literature of the subject was that each method had failed in other hands than those of its advocates and that each had been successful when carried out by those who had developed its application. The inference was that the skilful application of a well understood method by those knowing all its points was the thing to be desired and that the main object of nutrition being obtained the method was of secondary importance. He therefore urged the desirability of using whatever method was best adapted to the facilities and intelligence of their patients, and said that the first duty of the profession in striving to settle the problem of infant feeding was the elimination of doubtful milk by the education of public opinion —A brief discussion of the paper followed and a vote of thanks to Dr Lister brought the proceedings to a close

---

[1] THE LANCET Nov 15th 1902, p. 1329

GLASGOW SOUTHERN MEDICAL SOCIETY —A meeting of this society was held recently, Dr Duncan Macgilvray the President, being in the chair —Dr W F Somerville gave a demonstration of the Curative Properties of High frequency Currents in all conditions attributable to Retrogressive Changes in the Nervous System A number of patients were present whose ailments had either been cured or greatly relieved by a course of this treatment. One patient who had suffered from peculiarly obstinate sciatica and was on the present occasion accompanied by his family medical attendant gave a graphic account of the speedy and complete relief which he had obtained under the high frequency current. Among the cases shown were some in which chronic eczema due to varicose veins had quite healed under this treatment and one in which a large area that had been occupied by scrofuloderma had almost healed. An electric couch was also shown and a practical demonstration of high frequency currents was given

ÆSCULAPIAN SOCIETY —A meeting of this society was held on March 6th, Dr Thomas G Stevens, the President, being in the chair —Dr J S Risien Russell read a paper on Early and Anomalous Signs of Tabes Dorsalis. He said that probably no clinical picture was better recognised than that of the ordinary well developed ataxic patient. But there were others that were less distinct and for the diagnosis of these a systematic examination of the nervous system must be made The knee-jerks might be present and ataxy absent and yet a diagnosis of tabes be made , for the Achilles jerk might be absent and patchy analgesia present on the trunk, inner side of the forearm or the front of the legs, or the pupils be irregular immobile or sluggish, or optic atrophy be present though the vision was not defective noticeably to the patient Some cases commenced with bladder hesitancy others with gastric crises or herpes zoster might be the earliest sign Auditory vertigo, tinnitus, and deafness might be early signs of tabes

Reviews and Notices of Books.

The Diseases of Infancy and Childhood By L EMMETT HOLT M.D , LL.D Second edition revised and enlarged. With 223 Illustrations London Henry Kimpton 1903. Pp 1161 Price 25s

THE second edition of Dr L. Emmett Holt's work on the diseases of infancy and childhood departs but little from the general scheme of arrangement which rendered the first edition such a valuable work of reference for those who take an interest in, or make a specialty of, the important branch of medicine included in the title Conformably with the recent growth of knowledge in the department of the feeding of infants the chapters on this subject have been entirely rewritten and much new material has been added, while 21 additional illustrations contribute largely to the clearness and vividness of the clinical descriptions

Many of the reforms in our methods of feeding infants can be traced so clearly to the knowledge disseminated through the medium of the first edition of this popular work that the interest of readers will naturally centre in those portions of the new edition which deal with this subject. Among the methods of artificial feeding Dr Holt considers that the American or percentage system, as conducted in the Walker Gordon milk laboratories, is the best, ranking next to breast-feeding in usefulness and trustworthiness Of this method he remarks on p 186 "My own results have steadily improved each year as I have come to understand more clearly the indications for using the different changes in the milk which the laboratory has made possible. I have therefore no hesitation in placing it when intelligently used next to maternal nursing " Considerable space is devoted by the author to the description of this method which has been, since the publication of the first edition, placed on an even more scientific and substantial basis. The chief improvement recorded in this method lies in the possibility of varying the relative proportions of the caseinogen and lactalbumin of cow's milk. This extension of the method has very important bearings inasmuch as it is the inability on the part of infants to digest the casein of cow's milk which sometimes renders the ordinary modifications of milk absolutely futile in treating difficult cases of indigestion. The laboratory method of feeding has not always proved a success in this country and the reason for a certain proportion of the failures is doubtless because many persons have hastened to adopt this new method without thoroughly understanding the principles which underlie its scientific application. On this point Dr Holt remarks that "those whose knowledge of laboratory feeding consists only in the acquisition of a few formulas which are supposed to be appropriate for the early, middle, or late period of infancy are in little better position than one who feeds all children under his care on Dr A.'s or Dr B 's mixture or upon any of the commercial infant foods The results will probably be about the same. An equally improper way of using the laboratory is that of those physicians who know nothing of milk percentages and care less and who simply write, as I have known many to do, such directions as the following —'Send milk suitable for three months old baby ' In this way all the advantages of laboratory feeding are missed, and its fundamental principle violated, which is for the physician to prescribe a food adapted to the child's digestion at the time " Although Dr Holt places in the front rank this system of feeding which depends on the assistance of a milk laboratory he nevertheless maintains that with sufficient care and attention to certain details a degree of accuracy sufficient for all practical purposes can be secured by a method of home modification. This admission is especially important for practitioners in this country who are unable in the great majority of cases to avail themselves of the services of a properly equipped milk laboratory

The treatment of the symptoms of infancy by the modification of food rather than by drugs is even more strongly insisted upon in this edition than was the case when Dr Holt originally published his book some few years ago , in fact, as far as infancy itself is concerned the only logical inference which can be drawn from Dr Holt's teaching is that in the vast majority of instances those conditions which are not amenable to this form of treatment or to hygienic measures are not amenable to any other The diseases of infancy are mainly dependent upon disordered conditions of nutrition attributable doubtless in the majority of cases to faulty digestion and inefficient assimilation of food from the alimentary tract owing to the inappropriate character therefore, that the subject of chemical pathology is approached in accordance with the latest developments A rapid glance through the somewhat closely printed pages shows that this is so At the end of each lecture a list of the literature on the subjects treated is printed and the literature referred to is of quite recent date. In the chapter on Water and the Inorganic Salts the author suspects that the constant use of carbonated waters is sometimes harmful in several ways, as through local irritant action or through an accumulation of gas in the stomach favourable to the production of atony He points out that in the case of the dog the introduction of large volumes of carbon dioxide into the stomach and intestine is quickly followed by a decided alteration in the reaction of the urine, acid urine becoming rapidly neutral or alkaline. Further, it is stated that clinical experience has shown that there are some persons in whom uric acid calculi are more rapidly formed when carbonated waters are used than when "still" waters are used In the same chapter there is an excellent disquisition on alkaline waters and purgative saline waters The lectures obviously deal largely with the practical side of the subject, but, on the whole, we think that the author has entered somewhat too strongly into controversy The volume is a very handy one for students and practitioners, covering a vast range of subjects within comparatively small compass, and the details are presented in a decidedly bright and intelligible manner

Analytical Records
FROM
THE LANCET LABORATORY

HÆMOGALLOLES

(KASSLER AND WOLFF 101 FLEET-STREET LONDON E C)

HÆMOGALLOL is the name given to a substance produced from hæmoglobin by the action of the reducing substance gallic acid The effect of gallic acid is to remove one atom of oxygen from each molecule of hæmoglobin It follows that the product hæmogallol contains a larger percentage of iron than does pure hæmoglobin. Our analysis gave the percentage of iron (Fe) as 0 19 It is a reddish brown powder which may be conveniently administered inclosed in capsules (hæmogalloles) Clinical trials show that this form of iron is readily assimilated without causing disturbance in the alimentary canal. It has been employed with good results, according to reports from German clinics, in anæmic conditions It would appear to be an excellent form of iron in those cases in which that metal is indicated.

(1) "IRRESISTIBLE" AND (2) BRIGADE" WHISKIES

(HATCH MANSFIELD AND CO LIMITED COCKSPUR-STREET PALL MALL, LONDON S W)

1 The analysis of this whisky was as follows extractives, 1 40 per cent, mineral matter 0 01 per cent, and alcohol by weight 37 67 per cent., by volume 44 79 per cent. equal to proof spirit 78 50 per cent In regard to secondary products the following were the results per hectolitre of absolute alcohol acidity in terms of acetic acid, 53 52 grammes, aldehydes, 18 57 grammes, furfural, 4 46 grammes, ethers reckoned as ethyl acetate, 73 07 grammes, and higher alcohols, 89 20 grammes This whisky gives results consistent with the description that it is 'blended," while its somewhat high proportion of acidity and ethers indicates that it has been matured in sherry casks. The spirit has a delicate rather than a full malty flavour It is entirely free from the physiologically bad products of immature whisky 2. The analysis of this whisky was as follows extractives, 1 00 per cent, mineral matter, 0 01 per cent, and alcohol, by weight 33 22 per cent, by volume 45 41 per cent. equal to proof spirit 79 57 per cent. On determining the amounts of secondary products the following were the results given in grammes per hectolitre of absolute alcohol acidity in terms of acetic acid, 39 60 grammes; aldehydes, 15 70 grammes, furfural, 3 14 grammes, ethers as ethyl acetate, 49 32 grammes, and higher alcohols, 73 26 grammes. These results indicate that this whisky has been stored for a shorter period than the previous specimen and, moreover, that it has been more freely blended. The amount of ethers coupled with the acidity would, however, indicate that it has been stored in sherry casks The flavour is only slightly malty, but the whisky is free from raw products

KRONENQUELLE MINERAL WATER.

(SCHACHT WARNER AND CO 55 FORE STREET LONDON E.C)

The waters of Kronenquelle at Salzbrunn in Silesia are well known. They belong to the mildly saline and slightly carbonated class According to our examination, however, Kronenquelle water may also take a place in the category of lithiated waters, for, according to spectroscopical examination, this water contained a distinct amount of lithia. Further, on concentrating a quarter of a litre and eliminating the calcium and sodium salts a distinct precipitate of phosphate of lithium was obtained on adding a solution of sodium phosphate The character of the water may be judged from the following analysis which we made total mineral matter 2 10 grammes per litre, carbonate of soda, 0 837 gramme per litre, carbonate of lime (with magnesia), 0·685 gramme per litre, and sodium chloride, 0 16 gramme per litre The water contains only a slight excess of carbonic acid gas. It is agreeable to the taste and has a peculiar cleansing sensation in the mouth, owing doubtless to the alkaline carbonate. The water has been used in the treatment of gout and it is no doubt useful when a course of alkaline lithiated water is indicated

NON ALCOHOLIC BEER.

(H. B MAY DYSON'S-LANE NURSERIES UPPER EDMONTON LONDON N)

Though it is not strictly true to describe this beer as absolutely non alcoholic, yet it contains, according to our examination, less than 2 per cent of proof spirit, which is within the Excise limit. It contains nearly 3 per cent. of malt extractives The beer is agreeable to the taste, having a malty flavour and the bitter taste of the hop It is a good deal lower in alcoholic strength than lager beer, while it certainly has similar refreshing qualities.

STERILISED SWISS MILK, JURA BRAN

(THE SWISS MILK SOCIETY PENINSULAR HOUSE, MONUMENT STREET LONDON E.C)

The analysis of this milk was as follows total solids, 12 70 per cent, fat, 3 69 per cent., and mineral matter, 0 78 per cent. The milk is thus of excellent quality with a satisfactory percentage of cream. The milk was quite sterile, a result which is all the more satisfactory since the flavour was that of fresh milk. There was an entire absence of 'scalded" flavour We could find no indication of metallic contamination and it is stated that the bottom of the tin is not soldered, so that the milk is not burnt in the hermetically sealing process

VARIOUS SOAPS

(E. COOK AND CO EAST LONDON SOAP WORKS BOW LONDON E.)

On examination the toilet soaps submitted proved to contain an excellently pure soap basis and in no instance was any evidence obtained of free alkali. Amongst those examined were baby soap, white rose and cucumber soap, rose soap, honey soap, oatmeal soap, butter milk soap, glycerine and cucumber soap, almond and glycerine soap, white lily soap and rose and cucumber soap All the foregoing are admirably adapted for toilet purposes, they are economical in use and contain a minimum of moisture and are free from irritants. A similarly excellent soap basis is employed in the preparation of the medicated soaps containing respectively coal tar and carbolic acid. Finally, we have examined three soaps—namely, paraffin soap, petroleum soap, and lightning cleanser—which are made for ordinary household use. We found them powerfully detergent and the soaps containing petroleum and ability of Professor Zittel in writing text-books on palæontology and to the discrimination and energy of Professor Eastman and his editorial colleagues

---

LIBRARY TABLE

Obstinate Hiccough By L F B KNUTHSEN, M D Edin. London J and A. Churchill. 1902 Pp 169 Price 6s — This publication is a graduation thesis and, like many other theses of the same nature, is the result of a certain amount of laborious work in the collocation of facts but is quite lacking in anything suggestive of originality or research. The author gives a long and very detailed account of a case of severe hiccough which came under his own care and which proved fatal, and he then proceeds to cite all the cases of hiccough which have been reported in English and foreign journals and which he has compiled doubtless with much labour, the cases amounting altogether to over 150 These form a sufficiently interesting record and show the great multiplicity and variety of drugs and methods of treatment that have been adopted at different times, none of which have proved specific and trustworthy for all conditions of hiccough, even when the trouble was due apparently to the same cause The author then deals briefly with the anatomy, physiology, pathology, and treatment of hiccough. He gives it as his opinion, without any very serious arguments to support it, that the pneumogastric is the nerve most directly concerned in hiccough. Dr Knuthsen has nothing more original to suggest under "treatment" than the somewhat threadworn platitude that the condition underlying the symptom of hiccough should be first sought and treated, and only when a *prima causa* fails to disclose itself should the hiccough be treated as a disease *per se* The treatise ends with a catalogue of all the drugs and methods of treatment that have been used to combat hiccough with references to the cases in which they have been employed

Lehrbuch der Anorganischen Chemie Von Dr H ERDMANN Dritte Auflage, mit 291 Abbildungen, 99 Tabellen, einer Rechentafel, und sechs farbigen Tafeln. Braunschweig Druck und Verlag von Friedrich Vieweg und Sohn. 1902. Pp 788 Price 15 marks. (*Manual of Inorganic Chemistry* By Dr H. ERDMANN With 291 illustrations, 99 tables, a reckoning table, and six coloured plates.)—This is the third edition of a well known German manual. In our notice of the previous edition we pointed out that the author's plan was to present the mathematical aspects of chemical science before dealing with rudimentary facts We always maintain that the student should be made familiar with a few facts by experiments under his own observation before discussing theoretical principles The present edition has been decidedly enlarged, 30 more pages having been added, while the number of illustrations and tables has been materially increased We can only repeat what we wrote in a notice of the second edition, published in THE LANCET of Feb 9th, 1901, that although a "Lehrbuch," the author has managed to give within its covers a very comprehensive and lucid treatment of the subject and that the work is thoroughly up to date, ample references being made to the standards of atomic weight which have recently been codified by well known authorities. The coloured illustrations are admirable and refer chiefly to the spectra of the rare elements Since the second edition was issued we observe that the author has resigned his professorship at Halle and has become a professor in the Royal Technical High Schools in Berlin.

Experimentelle Beiträge zur Pathologie des Blutes (*Experimental Contributions to the Pathology of the Blood*) By Dr P SCHMIDT With four lithographic plates Jena Gustav Fischer 1902. Pp 42 Price 3s —This treatise is devoted chiefly to an inquiry into the nature and origin of the basophile granules in red corpuscles observed in certain conditions of anæmia. After a brief *résumé* of previous research on the subject Dr P Schmidt gives an account of his own work and then in discussing the whole question compares his results with those of other workers. He obtained the phenomenon of basophile granulation most readily and certainly in rabbits and guinea pigs after subcutaneous injections of phenyl hydrazin From his own researches the author is led to the conclusion that these granules are of nuclear origin and are for the most part produced by the division of the nucleus which precedes the regeneration and multiplication of the corpuscles in conditions of anæmia He finds them closely associated with the appearance of normoblasts and polychromatism in the blood In this view he is opposed to E Grawitz who regards the granules as degeneration products of the hæmoglobin contents of the corpuscles The author meets the main objection of E Grawitz that this basophile granulation is not found in the blood forming centres, such as bone marrow and the spleen, by pointing out that even the nuclei of normoblasts and of marrow cells in these centres stain very feebly, and considers, therefore, that the inability to establish the presence of this granulation in marrow may be due to inefficient methods of staining He states, moreover, that he has actually found undoubted evidence of basophile granulation in the corpuscles of normal bone marrow on one occasion. His discussion of the whole subject is interesting, but it cannot be said that the conclusions which he draws from his experimental data are entirely convincing

Ferments and their Actions By CARL OPPENHEIMER, M D, Ph D Translated from the German by C AINSWORTH MITCHELL, B A Oxon., F I C London Charles Griffin and Co, Limited 1901 Pp 343.—The introductory part of this work is devoted largely to what may be termed the polemics of fermentation. The author has made an attempt "to formulate a comprehensive conception of the notion 'ferment' on a dynamic basis and starting from this standpoint to regard the theory of ferments as a theoretically closed field of discussion." Thus he has treated the enzymes and organised ferments as a connected whole. Basing his attitude upon the researches of E Buchner, which practically removed the old distinction between organised and unorganised ferments, he starts with a comprehensive conception of a ferment which he says can only be of a dynamical character He decides, therefore, that enzymic processes are of a chemically exothermic kind. He then describes the mode of action of various ferments and closes with a section in the general part of the work on the Importance of Ferments to the Vital Processes. The special part of the work is divided into (*a*) the hydrolytic ferments, of which pepsin is a type, and (*b*) the oxidising ferments, of which yeast with the diastases is a type. There are very many points in regard to the nature and action of ferments which require further elucidation and already in the light of fresh researches several authorities on the subject find that they have to shift their ground The translator in his preface points out the view of the author that a ferment can never effect a synthetic process, whereas comparatively recent researches have shown that the action of lipase is a reversible one The work forms a very convenient and handy text book of reference on the subject.

Lectures on Chemical Pathology By C A. HERTER, Professor of Pathological Chemistry, University and Bellevue Medical School, New York. London Smith, Elder, and Co 1902. Pp 461. Price 7s 6d —With a few exceptions this volume contains the subject matter of a series of lectures delivered by the author at the University and Bellevue Hospital Medical College, New York, during the sessions of 1899–1900 and 1900–01. It may be assumed,

LONDON SATURDAY, MARCH 14, 1903

The Vaccination Acts

MR. BALFOUR has informed Parliament that there is to be no new Vaccination Bill this session and that the Act of 1898 is to be renewed, though probably only for a single year This probability carries with it the possibility or perhaps more than the possibility, of a Vaccination Bill being introduced in the next session of Parliament The Prime Minister vouchsafed no reason whatever either for the non introduction of a new Bill this year or for the proposed continuance of the 1898 Act for only a single year As regards the latter point, we rather appreciate this non committal attitude. When the Bill of 1898 was in the House of Lords it will be recollected that it was passed only owing to the hope held out by the Government that a Revaccination Bill would be introduced in the following session. That hope remains unfulfilled and we trust that Mr BALFOUR and his colleagues are a little ashamed of having in effect misled Parliament on that occasion. It is certainly better for them on such a question to say less than they mean rather than more and possibly the present reticence is more hopeful than the former comparative effusiveness

It has, we think, been the contention of Dr F T BOND, secretary of the Jenner Society, that there ought to be a year's delay before the introduction of a new Bill and that the year should be taken advantage of to hold some kind of inquiry into the working of the 1898 Act. There is, however, no Parliamentary hint of any formal inquiry, and indeed it may safely be assumed that the Local Government Board has during the whole period of the operation of the most recent Act been carefully noting alike its virtues and its defects In these circumstances there seems to be no strong reason for any other inquiry, but at the same time it is quite possible that if the actual drafting of a Bill has already been undertaken at Whitehall questions may have arisen which cannot be settled offhand and which, therefore, may usefully be considered at greater leisure, so as to have everything in readiness for the introduction of a well thought-out measure at the beginning of the next session of Parliament. The relation of the new educational authorities to the administration of the Vaccination Acts, and especially to any provision relating to revaccination, is a question which may require careful discussion and consultation between the central health authorities and the central education authorities We are very willing to hope that reasons such as these, together with pressure of public business in other directions, have largely entered into the Government's decision to defer any fresh legislation on this important subject

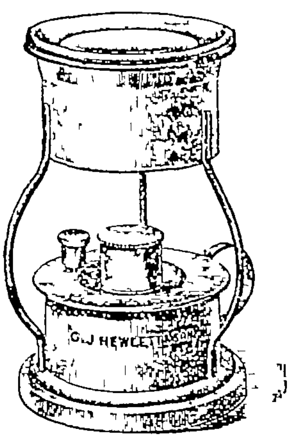
Meanwhile, evidence continues to accumulate of the need for legislation. It is a humiliating confession that though we know quite well how to prevent small pox there yet should have been in the provinces of England since the beginning of the year between 2000 and 3000 cases of the disease, as Sir MICHAEL FOSTER has elicited by means of a question in Parliament, and that in 1901–02 there should have been about 10,000 cases in London, and in 1900–02 much over 2000 cases in Glasgow, and a few years earlier very nearly 2000 cases in Gloucester Every one of these facts is a reproach to the nation and to its methods of government. At a time when the protection of the public health is receiving more attention than ever before when elaborate efforts are being made to prevent tuberculosis, when we are deploring our comparative helplessness to check the spread of cancer and are entering on most careful research in the hope of removing our inability concerning it,—while all this is being done there yet remains the paradox that as a nation we knowingly permit one of the foulest diseases that has ever afflicted humanity to exact its yearly toll of sickness and of death, accompanied by all the incidental evils that small-pox invariably carries in its train, though there lies ready to our hand an easy and simple and very safe method of reducing its ravages practically to the vanishing point. Judging from his freely expressed views on the whole subject the President of the Local Government Board is fully alive to these anomalies and to the national disgrace under which we at present rest in this matter Indeed, one of the best hopes of an early removal of this scandal from our public health administration is to be found in the fact that the Minister who is at the head of the department which has special charge of such questions is himself so keenly conscious of the utter indefensibility of the present position.

Though the whole subject of vaccination is of infinitely more importance to the public than to the profession of medicine, there is yet one body of medical men who have a grievance to suffer so long as the present system continues. Elsewhere in this issue of THE LANCET (p. 754) there is reported a series of resolutions adopted at a meeting of public vaccinators at Plymouth It is not necessary to refer to all the points which they raise, but obviously they are asking only common justice in requesting that public vaccinators should be as independent in position as are vaccination officers. At present the latter cannot be dismissed except with the consent of the Local Government Board, while the former are regarded as being only under contract terminable by four weeks notice. If a competent medical man, with the usual responsibilities of life to face, is to devote any large portion of his time to special work such as vaccination under appointment by any local body it is obvious that he should have reasonable security for the permanence of his position. Days or hours periodically devoted to vaccination are so much time taken from other branches of professional work and a man who is capriciously deprived of office cannot immediately substitute for the lost occupation such employment as he could have secured in the time given to official duty in former years Proper and impartial consideration of questions of emolument between employer and employed cannot be carried on under constant threat of dismissal from office in the event of non acceptance of offered terms. What the exact remuneration of public vaccinators should be is a complicated question on which we do not profess to enter here. In fixing fees under the described and contain some free alkali. The lightning cleanser, however, gave no reaction distinctive of alkaline excess These soaps contain no foreign ingredients beyond those described, they are free from objectionable resins and silicates.

New Inventions.

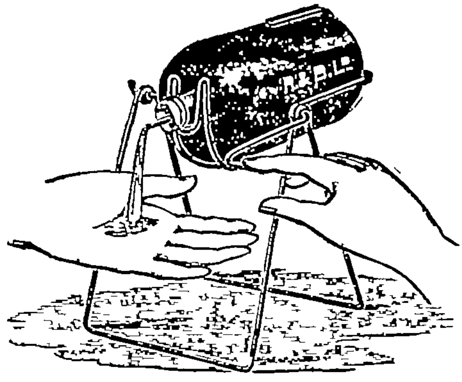
UNNA'S PASTES AND HOT WATER BATH

THE "pastes" consist of gelatin discs containing zinc oxide, boric acid ichthyol, iodoform, resorcin, carbolic acid, or other agents used in dermatological practice. The discs loaded with these medicaments are somewhat larger than a five-shilling piece and about three times as thick In practice the disc is placed in a water bath specially constructed for the purpose. As shown in the illustration the water bath consists of a spirit lamp over which is placed a water-container, upon the top of which a shallow porcelain dish rests The discs are placed in the porcelain dish in which, as soon as the water boils, they melt, furnishing a liquid paste which may be painted on the affected part with a camel hair pencil. This method of preparing applications for dermatological use offers several obvious advantages. The apparatus and discs are supplied by Messrs. C J Hewlett and Sons, 40, 41, and 42, Charlotte street, London, E.C



AN ASEPTIC SOAP CRADLE

THE accompanying figure illustrates a very simple and useful adjunct to the wash basin for the use of medical men and others. The apparatus consists of a base constructed of stout wire in triangular form On the apex of this triangle a wire framework adapted for holding a bottle swings and by means of a handle the bottle may be tipped and a supply of liquid soap obtained The quantity of soap discharged can easily be regulated The manner of using the apparatus will be seen in the accompanying illustration. The soap cradle may also be attached to the wall. A cork with double perforation is fitted into the neck of the bottle A glass tube is passed through one of the perforations to within a short distance from the bottom of the bottle Through the other perforation a short piece of glass tube is fitted The liquid soap passes out of the short tube, air taking its place through the longer tube The bottle is made of brown non actinic glass and the label consists of sand blast lettering The apparatus is supplied by Messrs Reynolds and Branson, 13, Briggate, Leeds.



A NEW SPLINT FOR COLLES'S FRACTURE.

MR. JAMES S ASHE, of the Adelaide Hospital, Dublin, has invented a new splint for the above fracture for which the following advantages are claimed. It can be used for both arms. An extension movement can be obtained, together with any degree of adduction or abduction. It consists of two parts (1) the splint proper and (2) the crutch. The splint proper is a piece of wood about five inches by three inches by a quarter of an inch with a screw at one end which allows the crutch to be racked out to any degree according to the size of the arm, &c., and there fixed. The crutch is T shaped and is composed of metal, the cross piece being wood is the part held by the hand, the limb has a cut-out groove in it which slides up and down on the screw of the splint proper, another screw allowing it to be fixed at any angle The accompanying illustration explains the working Messrs. Down Brothers, Limited, of St. Thomas's street, London, S E, are the makers.

FOREIGN DEPARTMENT

ANALYSIS OF FOREIGN MEDICAL JOURNALS.

REVUE MEDICALE—JAN

Croton Tiglium.

From some researches made by M. CAVENTOU on this vegetable, he has ascertained that the oil extracted from it, which has become extensively used in this country, is precisely similar to an oil procured from the seeds of a plant, called in France, *Pignon d'Inde*, and, therefore, *suggests* it as a substitute for the former M.M Recamier and Kapelar have made some comparative experiments with the two oils, and have shown that their action is identically the same.

Thridace

The juice of the *lettuce* introduced into practice by Dr Duncan, and highly extolled by him as a substitute for opium, has been lately examined by M. François, and he has discovered what he considers to be the active principle of the plant, to which he has given the name of Thridace.

On the Use of Citric Acid in Uterine Hæmorrhage

In No 8 of the present volume we gave an abstract of a paper read on this subject at the Royal Academy of Medicine on the 13th of January Dr Macleod, considering the introduction of a lemon into the cavity of the uterus to be a very novel, not to say an ingenious procedure, submitted it to the notice of the Westminster Medical Society, for the purpose, we suppose, of eliciting the opinions of the persons present respecting it. A discussion ensued, Dr Granville expressed himself as opposed to the remedy, considering it to be unsafe and ineffectual Some gentlemen conceived that there would be great difficulty in getting the lemon out It might be introduced easily enough, but how was it to be extracted? A silence followed, the question was so important, that it required the most serious deliberation, and such it received! With the greatest imaginable gravity, and with the air of one "profoundly skill'd in analytick" Dr Copland arose, *Dr Copland, Consulting Physician to the Queen's Lying in Hospital cum multis aliis honoribus*, modestly *suggested* 'that a small bit of string should be fastened to the extremity of the decorticated lemon, by the aid of which it might be safely withdrawn" !!

The suggestion was excellent, it dissipated all doubt and difficulty, it was the very *quod erat demonstrandum* of the question, and the Society testified their approbation by great laughter and applause required to elucidate the difficulties now existing. Bronchopneumonia is unfortunately not a rare disease and consequently plenty of material can be obtained for clinical observation, and if other observers confirm the statement that cases of this disease can definitely be divided into two groups great assistance will be derived in regard to treatment, and also in reference to the prognosis, in individual cases.

◆

The Working of the Midwives Act

THE remarks made by certain of the speakers at the meeting recently convened by supporters of the Midwives Act, under the chairmanship of Sir MICHAEL FOSTER, require a little consideration from us. It will be seen from the report of this meeting published in THE LANCET of March 7th, p. 679, that the supporters of the measure, having succeeded in Parliament in securing legislation more or less in accordance with their wishes, do not look forward with entire confidence to the working of the Act when its application comes into force. They wish, therefore, to pre-concert measures which shall achieve the object for which the Act has been framed—viz., the relief of the parturient poor, and in any such endeavour they will have the sympathy of the medical profession shown none the less cordially because the majority of medical practitioners, like ourselves, think it probable that the Midwives Act renders subsidiary efforts in behalf of the parturient poor particularly needful.

In calling to mind the main provisions of the Act it appears to us that the consoling feature of its progress through Parliament was the amendment which caused the inclusion of a clause penalising the practice of midwifery by those not certified under the Act. The inclusion of this penalty clause saved the Act from being largely ineffective. No woman is to be certified under the Act as a midwife unless she has complied with rules and regulations that are to be formulated by a Central Midwives Board the formation of which has been settled upon and the duties of which will soon commence. The Central Midwives Board besides regulating the course of training of midwives and appointing examiners, will publish annually a roll of duly certificated midwives and will decide upon the admission to the roll of women already practising as midwives. Every council of a county or county borough throughout England and Wales is to be the local supervising authority over midwives within its area. Every woman certified under the Act before holding herself out as a midwife or beginning to practise must give notice in writing to the local supervising authority. In this way the women certified as midwives under the Act will be brought under local and general control, so that the public will feel that their employment, so long as they keep within their sphere of knowledge, is unattended with the risk entailed by the services of the old time monthly nurse. But if this qualified measure of security is counterbalanced by a drying up of the supply of midwifery nurses the benefit derived by the public is surely a shadowy one. The objections which we and a large majority of the medical profession have always had to legislation for the registration or certification of midwives have been often set out in our columns. We think it opportune to allude briefly to them so that when the new Central Midwives Board begins to work its members may take all steps to guard the public. The duties of a midwife are not clearly defined in the Act, nor is there any special provision made to secure that she shall immediately seek the aid of a medical man when confronted with pathological conditions that are beyond her skill. There can be little doubt that in the eyes of that large class for whose welfare she has been called into being the certificated midwife with her limited training will rank as the equal of the medical man. Services will be asked of her that can only safely be performed by those who have full medical and surgical experience. Acquaintance with one particular physiological process when it is normally performed must not, in the public interest, be allowed to qualify a certificated midwife to play the part of a general practitioner. We shall rejoice as heartily as any promoter of the Midwives Act at the disappearance of the dirty GAMP, and shall hail with delight, giving credit where the credit is due, any distinct abatement in infant mortality that can be traced to its working, but we would urge upon the Central Midwives Board the necessity of making certificated midwives understand that there are limitations to their duties and responsibilities.

At the meeting already alluded to which was convened by Mrs. HEYWOOD JOHNSTONE at the Grosvenor crescent Club, it was evident that the chief difficulty anticipated by the supporters of the Act relates to the supply of midwives in rural districts. The anticipation is likely to be well founded. The number of certificated midwives available in 1903 will largely depend upon the freedom with which the Central Midwives Board grants certificates to women who are now gaining a living as monthly nurses. If the Central Midwives Board adopts a low standard of training and character there will be as many midwives as at present, but the Act will be a fiasco. If, on the other hand, it insists upon good character and efficient training in obstetrics, then the dearth anticipated will be no doubt severely felt, especially in rural districts. As Dr. R. BOXALL has pointed out trained midwifery nurses are with difficulty induced to exercise their calling in the remote country parts. The first step on the part of the board towards securing a sufficient number of midwives should be to find out through the medical men and clergymen of the various districts which of the women now acting as midwives can with safety be certificated. Then with the aid of the medical man those regions left stranded by the removal of incompetent midwives should form themselves into self supporting associations to keep the services of a properly trained midwife for attendance on the parturient poor. Such a nurse should know when to ask the assistance of a medical man. This plan is more or less the one suggested by Mrs. HEYWOOD JOHNSTONE and forms the only solution, so far as we can see, of the impending difficulty. In short, the less that the Act interferes in country districts with the existing condition of things the better chance it will have of not breaking down altogether in some of its operations, but, also, the less chance will it have of remedying the evils which justify its presence on the statute book. This can hardly be called a strong argument for new legislation.

Act of 1898 it is quite possible that payment for revaccination during epidemics, as distinguished from primary vaccination at ordinary times, did not receive sufficient consideration, and boards of guardians have a right to express their views on such a subject What we insist on is, however, that due discussion of these points cannot but be hampered by the present utterly unsatisfactory tenure of office.

In the resolutions referred to we are glad to note that the public vaccinators recognise the right of the ordinary medical practitioner to consideration by the Government in respect of vaccination work duly and efficiently performed. The proposal is that every practitioner should receive a fee for every certificate of vaccination performed in accordance with the standard of efficiency recognised for public vaccination That seems on the face of it a reasonable solution of a question which is not unattended by difficulty, and it is to be hoped that whatever legislation be introduced on the whole subject the Association of Public Vaccinators will take steps to impress on all its members their duty to exercise the utmost discretion in the practice of domiciliary vaccination and to avoid all reasonable ground for criticism by the medical attendants of the households into which they are called in the course of their official duties.

◆

Broncho-pneumonia

THE etiology and pathology of lobar pneumonia are now thoroughly understood and although this affection has usually been considered a pulmonary disease yet many authorities consider that it should be placed amongst the specific fevers and perhaps the term "pneumonic fever" would be a more apt one than "pneumonia."

With regard to broncho-pneumonia—otherwise called "catarrhal," "lobular," or "patchy pneumonia"—less unanimity prevails Professor E AUFRECHT[1] considers that a catarrhal inflammation of the mucous membrane of the finer and finest bronchi is an absolute condition upon which broncho pneumonia depends, in this view he is supported probably by most observers Dr SAMUEL WEST,[2] however considers that cases of broncho-pneumonia in children may be divided into two groups according as the disease has been preceded by bronchitis or not, and he calls these groups "primary" or "idiopathic" and "secondary" respectively Broncho pneumonia, whether primary or secondary, is met with chiefly in the early years of childhood and becomes less and less frequent as the fourth and fifth years approach It can hardly be said that children are less susceptible to bronchitis after the age of four years than before, yet broncho-pneumonia, as has just been pointed out, becomes much less frequent after that age. If lobar pneumonia is due to a specific infection it scarcely seems reasonable to assert, as Dr WEST points out, that children under four years of age are less susceptible than children above that age, especially as the pneumococcus is found almost as frequently in the broncho pneumonia of little children as it is in the lobar pneumonia of the adult. From this fact in the bacteriology of the disease the suggestion arises that the form which the inflammation takes in the young child depends upon some peculiarities in the lungs as compared with those of the adult. Dr WEST maintains that the respiratory mechanism in children presents many such peculiarities. The chest walls are elastic and yielding owing to the incomplete ossification of the ribs and the thorax approaches the cylindrical in form, the type of respiration is diaphragmatic rather than costal and remains so up to about the sixth or seventh year In structure, also, the lungs of children present many notable differences from that which is found in the adult, thus, the trachea and main bronchi in the young child are much larger, the other branches are also larger in the child than in the adult, and occupy greater relative space, the air cells are smaller and the interstitial tissue of the lung is more abundant There are other differences which might also be mentioned, but those which we have named are sufficient to justify the suggestion that inflammation in the lungs of young children may assume a form unlike that which is seen in older patients Dr WEST, therefore, arrives at the conclusion that the same exciting cause—e g a pathogenic organism such as the pneumococcus—which in the adult and older children excites a lobar inflammation, in very young children usually causes a lobular inflammation If this contention is correct the distinction drawn between primary or idiopathic broncho pneumonia and secondary or catarrhal broncho-pneumonia requires to be carefully considered both on clinical and pathological grounds. In support of this classification Dr WEST records several cases illustrative of each group The instances which he relates differ considerably in their type and course and certainly corroborate his views The bacteriology of broncho pneumonia, so far as it is known, also testifies to the value of his theory He quotes the results of several observers and the evidence thus adduced shows that in secondary broncho pneumonia the streptococcus is the most frequent organism that is found, whilst in primary broncho pneumonia it is the pneumococcus, and it is further proved that in the latter affection the pneumococcus is almost as common as it is in the lobar pneumonia of adults

In dealing with the main differences between the morbid anatomy of croupous pneumonia and broncho pneumonia respectively, Professor AUFRECHT states very definitely that "catarrhal pneumonia never has a granular cut surface," and he also gives in great detail the microscopical conditions found in each variety of the disease, which, in his opinion, differ considerably Dr WEST, on the other hand, says "It is now well known that the microscopical distinctions often drawn between the minute lesions of lobar and lobular pneumonia cannot be regarded as absolute and that, for example, even the fibrin network which is so common in acute lobar pneumonia is not uncommon in acute broncho-pneumonia, while it may be absent in lobar pneumonia" The views which we have quoted will thus be seen to be somewhat diverse. We believe, however that modern research tends to corroborate the classification suggested by Dr WEST The division into primary and secondary varieties undoubtedly removes some of the difficulties which are felt at the bedside, but further investigations are siege which he undergoes at the hands of continental quidnuncs eager for the latest information as to the condition of his venerable patient. On the day before the great ceremony of March 4th he had to cut off all telephonic communication with his own residence, the assault of the said quidnuncs having previously been so persistent that they declined to accept as 'information' even the bulletin which he had authorised the members of his family to quote in reply to them! But, as he assured a friend quite lately, he forgets all these worries in the far more trying cares that beset his patient, whose self abnegation really grows with the demands made upon it and whose life seems inspired by the watchword of the great French ecclesiastic, 'Rest? we shall rest thro' Eternity!'"

---

[1] Professor Nothnagel's Encyclopædia of Practical Medicine.

[2] Diseases of the Organs of Respiration

THE FUTURE OF ST GEORGE'S HOSPITAL

WE have received from Mr C L. Todd, the secretary of St. George's Hospital, some papers which have been circulated among those interested in the matter relative to a proposal to remove the hospital from its present site to one of greater extent. The question is one that has been under debate in an informal way for some time among St. George's men. The papers give the reasons why some of the governors of the charity have proposed the removal of the hospital and these may be summarised by saying that the increasing difficulty of carrying on the work of the hospital in conformity with modern ideas, which has been for some years past increasing, has now become insuperable unless a considerable extension of the present site and buildings of the hospital can in some manner be obtained The amount of medical and surgical work done by means of the hospital beds has doubled during the past 30 years entailing a greatly increased staff of nurses, officers, and other employés, for all of whom additional accommodation has now to be found. The governors of the hospital have during the last 12 years made every effort, by rearrangement and enlargement of the existing buildings to provide this accommodation but the limits of practical extension have been reached The same story of inadequacy of space must be told of the out patients' department. This and all the various special departments of the hospital are suffering from want of room The proper quarters for an x ray installation, for systematic treatment by baths for electrical treatment, for the Finsen treatment of lupus, and for other modern therapeutical developments have to be found. With regard to the medical school, those who advocate removal point out that it has for years been suffering from the exiguity of its premises and prophesy that it will not be possible much longer to carry on educational work at Hyde Park Corner It will thus be seen that those who propose the removal of the hospital can make out a very strong case. But the same may be said for those who object to the revolutionary course. Those who would preserve St. George's Hospital in its present site hold that the site would not be insufficient for the purposes of the hospital alone if the nurses home and the medical school could be accommodated elsewhere It might be necessary to remodel the central block of the building but the expense of this and of rehousing the school and the staff taken together would be nothing compared to the expense of rebuilding a large general hospital on a new site in the west end of London. The extreme difficulty of finding a site large enough for the purpose anywhere in the west of London is obvious, while it is equally clear that any change which would remove St. George's Hospital far away from its present position would entirely alter its whole organisation, as well as deprive London of a receiving house for the numerous accidents in the parks and streets that converge at the west end of Piccadilly The governors of St. George's Hospital have an extremely difficult question before them, one, indeed, on the solution of which the whole future of a dignified and valuable London charity of many years' standing may depend. We are certain that they will discuss the *pros* and *cons* of the removal of the institution with all care and forethought They will receive a great deal of gratuitous advice, the cocksureness of which will always be proportionate to the ignorance of its donors But as this will probably be apparent to them they may be expected to disregard it. In one way the situation may be easier for those who desire to remain in their old quarters than it has been for some time The excavations of a tube railway have considerably reduced the value, at any rate temporarily of the houses in St. George's place immediately to the west of the hospital, so that extension in this direction is no longer out of the bounds of imagination on the score of expense

THE PREVALENCE OF SMALL-POX

CASES of small pox continue to be reported from various places in the north of England. The disease has broken out among navvies working at Harrogate Over 300 cases are under treatment at Liverpool and Salford and Leeds are also suffering Small pox has broken out in Winson Green Gaol, Birmingham, while Keighley, a great anti vaccination centre is also affected by an outbreak After all, there is no argument in favour of vaccination so cogent as an outbreak of small pox In the South of England six cases have occurred in one family at Braunton, Devonshire. The cases were of such a mild nature that the first four were considered to be chicken pox. The infection was apparently imported from Cardiff. An inquest was held by Mr Wynn Baxter on March 6th at the Whitechapel Infirmary upon the body of a man who was found in a dying condition in the street by a policeman The cause of death was hæmorrhagic small pox. Dr R Dudfield, medical officer of health of the borough of Paddington, has issued his report upon the epidemic which prevailed during 1901 and 1902 The outbreak in Paddington lasted for 14 months and in all 132 cases were notified. Of these 15 were notified in error so that only 117 cases are dealt with in the report The 117 cases occurred in 81 houses, 61 were males and 56 were females. With regard to vaccination state, "unvaccinated" includes both those who had never been vaccinated and those who were only vaccinated after infection The following table shows the vaccination state and age periods of the fatal cases —

Fatalities per 100 Cases of each Group

Ages	Unvaccinated	Vaccinated in infancy only	Revaccinated
0–15 years ..	50·0	—	—
15–30	42 8	4 3	—
30–45	50·0	22·2	25·0
45–60	—	16·6	100·0
60 years and upwards	—	—	—

At first sight the mortality percentage among the revaccinated cases looks alarming, but there were altogether only seven cases of small pox in this group Two were females and neither died, five were males and of these two died—one aged 43 years revaccinated 20 years previously and one aged 46 years revaccinated 25 years previously It is this case which brings the mortality of the 45–60 group up to 100 0, being the only revaccinated case in the group The other figures in the table speak for themselves. At all ages the cases, vaccination state, and deaths were as follows never vaccinated, 11 cases with six deaths, vaccinated after infection, six cases with two deaths, vaccinated in infancy only, 94 cases with 10 deaths, and revaccinated, seven cases with two deaths. One of these cases, an infant infected *in utero* and aged 13 days, was not notified and so is additional to the

Annotations.

"Ne quid nimis"

THE ROYAL MEDICAL BENEVOLENT COLLEGE

ON Wednesday, June 10th, H R.H the Prince of Wales will preside at a festival dinner of the Royal Medical Benevolent College in aid of the funds of the charity and in celebration of the jubilee of the laying of the foundation stone of the College. It is not to the credit of the medical profession that such a noble institution as the Royal Medical Benevolent College should have to plead so earnestly and so repeatedly for funds to carry on its splendid work. Had it not been for the dauntless courage and untiring efforts of a few medical men this good work would have been considerably curtailed and while the profession would have had a less effective charity both the profession and the public would have lost an educational institution of merit. We have so often urged the claims of the College that we hesitate again to remind our readers of the scope of its work, but we feel sure that all who love their profession and its institutions will bear with us in appealing to those who for one cause or another may have overlooked a charity which ought to be their peculiar care The Royal Medical Benevolent College provides pensions for aged medical men and the widows of medical men in reduced circumstances, together with a school open to all classes, but offering special advantages to the sons of medical men, 50 of whom are foundation scholars. There are 50 pensioners who receive £30 a year each. The 50 foundation scholars, we should mention, receive an education of the highest class and are boarded, clothed, and maintained at the expense of the College. For the benevolent side of the institution a sum of over £6000 is required annually and the greater part of this amount is derived from voluntary contributions. As we have already mentioned, the jubilee of the College is close at hand and in a building 50 years old it is not surprising to learn that considerable structural alterations have been found necessary and that sanitary defects have had to be remedied There is also a debt owing to the bankers of nearly £3000 To clear off these liabilities and to put a little money by are now the objects of the council and we feel sure that the medical profession will do its utmost in some measure to repay the kindness of his Royal Highness in presiding by subscribing the £10 000 for which the council is appealing as a jubilee fund. But if the Royal Medical Benevolent College is to take the place which it ought to take among the charities of the profession by continually enlarging its sphere of usefulness something more will be required than great efforts made at widely separated intervals of time The flow of charity must be a steadily increasing one from year to year In England alone there are over 20,000 registered medical men. If every one of these were to subscribe only 10*s* per annum it would mean that the income of the College would be £10 000 a year Ten shillings a year is not a large sum it is less than threepence per week, and with a banker's order given for the sum to be paid regularly the disbursement would scarcely be felt. But the united subscriptions would make a vast difference to the usefulness and power for good of the College

A PLUCKY DEED

AT the levée held on March 9th His Majesty the King presented Captain Herbert Cumming French, R.A.M.C., with the decoration of the Albert Medal, second class. The service for which this decoration was awarded was as follows. On Nov 17th, 1902, H.M. Transport *Wakool* was steaming through the Straits of Malacca at a rate of about 12 knots per hour when a native fireman jumped overboard Captain French, who was a passenger, immediately dived into the sea from the promenade deck, a height of about 36 feet, and swam to the place where the fireman had been last seen When, however, he reached the spot the man had sunk and Captain French, becoming exhausted by the weight of his clothing, had to make for a life-buoy Both men were eventually rescued by the life boat. A strong current runs at the place and Captain French ran great risk of being caught by the ship's screw and, in addition to this danger, sharks and water snakes are frequent in the Straits of Malacca. We congratulate Captain French on his plucky deed and the recognition of it at the hands of His Majesty

LEO XIII AND HIS JUBILEE

ONE of our Italian correspondents writes under date, Rome, March 7th —"The Pope seems destined to do credit to Italian medicine, from Celsus to Lapponi. True to the prescriptions laid down by the former in his famous first chapter, for the first 68 years of his life he lived as the Roman Hippocrates says every 'sanus homo qui et bene valet et suae spontis est' ought to live, 'partly in the country, partly in the town, and, oftener than not, in the open air He ought to yacht or hunt,' or allow himself the recreation of rod or gun In this latter form of outdoor exercise the Pope, when Archbishop of Perugia, was exceptionally proficient and after an enjoyable day on the Umbrian hill sides he would return with a heavy bag of red legged partridges for distribution among the hospitals of his diocese—a feat he thereafter celebrated in Catullian hendecasyllabics for the amusement of the dean and chapter From this life of the student alternating with that of the sportsman he passed, just 25 years ago, to the Vatican there, as supreme Pontiff, to play the part of 'prisoner' (with doors locked on the inside) and to assume the reins of an empire on which, if the sun never sets, a cloud ever hangs. It is at this stage that his body physician found his responsibilities really begin True, his august charge inherited the constitution and the wiry physique of a long line of mountaineers, advantages strengthened by plain living, high thinking, and out-door recreation, systematic without monotony But confinement even to 'a palace and a garden' on the least healthy of the hills of Rome involved a sudden change of habits, nay, a revolution in the *modus vivendi* which put the preceding 68 years of well ordered life to a severe test However, as Dr Lapponi himself is the first to admit, His Holiness is an exemplary patient, observing with promptitude and in entire good faith the prescriptions from time to time submitted to him and reinforcing the regimen with that best of all auxiliaries to the professional man, the will to live. It is thus that he performs feats of endurance, mental and physical, that would impose a formidable strain on men 20, or even 25, years his junior and that the ordeal of his pontifical jubilee on March 4th left him fatigued doubtless, but much less so than hundreds upon hundreds of the 60,000 spectators who from all parts of the world thronged St. Peter's for the ceremony Not that this marvellous vitality or resisting power ever lulls to sleep the vigilance of his body physician. On the contrary, Dr Lapponi, well aware how often in practice the unexpected happens, is never more alert than when all the omens seem to be most favourable and redoubles his precautions down to the minutest details, not only of diet and rest in the recumbent posture, but even of clothing and temperature and the transition from one suite of apartments to another He himself, indeed, is feelingly reminded in his own person—

> Quid valeant humeri quid ferre recusent

and complains, good humouredly enough, of the constant or else relegated to the small hours of the morning or at a time when the ordinary traffic practically ceases We should like to know what the effect of this heavy steam traffic is likely to be upon the various mains in the streets. The consequences that may arise from the crushing of these mains are really alarming, considering the close proximity of the water mains, gas mains, and the high pressure electric mains As long as the streets are to be permitted to the use of engines and wagons on the same scale as railroads we may well shudder at the awful possibilities of turning electric currents astray and of letting loose gas and water at the same time

CANCER "CURES"

IN the *Pall Mall Gazette* of Feb 27th a short article appeared which was called "A Triumph of Electricity" It concerned itself with the cure of cancer by "high frequency" electricity and the gist of it was that a "doctor" who lives "in a handsome house not a hundred miles from Hyde Park" and is "one of the first and foremost private medical men in this line" and "one who may in all truth be said to have advanced even a step or two further than any other" has discovered that "high frequency" is the cure for cancer. Reference is also made to the opening of a hospital for the application of his treatment. There are also in circulation just now a printed leaflet and a letter about the same matters and in these appears the name of Mr. E. A. Cloete Smith. He has a hospital not far from Hyde Park. The letter recommends the high frequency treatment of cancer as against the use of the Roentgen rays and mentions Mr. Smith as the skilled operator Considering the nature of cancer and the slow and laborious work which is being done in many quarters to try to solve the problem of finding a successful treatment for it—considering, too, the slight encouragement which is leading investigators forward into the x ray and other electrical methods in spite of many disappointments—it certainly seems that Mr Smith and his friends are doing much harm and little or no good by announcing that the disease can be cured, and that by high frequency electricity The facts about high frequency and cancer are that whereas some relief of pain and some temporary decrease of size in the tumour may be obtained by high frequency we are nevertheless baffled in the attempt to obtain anything which may be called a cure. Much more pains taking work has to be done before arriving at the goal and it is uncertain whether the desired result will be reached at all or not. Certainly it is not by proceedings like those of Mr Smith that success is to be found. The evidence in favour of the efficacy of the x rays is considerably stronger than any which can be adduced as yet for high frequency A few cases which have been reported of high frequency "cures" have proved to be fallacious and some at least of the patients reported as "cured" have died from a recurrence of their disease.

A QUESTION OF REMUNERATION UNDER THE POOR-LAW

A CORRESPONDENT who is medical officer to a workhouse, having received a letter from his board of guardians requesting him to attend at an early hour every day to examine the tramps in the casual wards before they leave, in order that cases of small pox may be detected in the earliest stage, asks us to give our opinion as to the amount of remuneration that he would be entitled to claim for the performance of so inconvenient, so constant, and, in this case of a gentleman engaged in general practice, so objectionable a duty It is somewhat beyond the limits of possibility to define the exact value of medical services and especially when they are of such a nature as those here indicated A knowledge of the appointments held under the board of guardians and of the class of the patients in the practice conducted by the surgeon concerned would be necessary for the making of a correct appraisement. The most important factor in the position will be found in the terms of the contract between our correspondent and his guardians At his appointment as medical officer were the casual wards put in his care? In other words, has he visited sick casuals as part of his duty at the workhouse? If the answers to these questions be in the affirmative then it will appear that the guardians, under the powers given by Article 207 of the general consolidated order can call upon him to visit the wards at the hours which they may fix and without payment other than the salary otherwise given. On the contrary, if the duty of visiting the patients in the casual wards has been added to the duties of the workhouse medical officer, or if the number of such visits was agreed upon originally and has now been increased, then our correspondent will have a right to claim further remuneration. To enable him to estimate the value of the extra services demanded from him it may be mentioned that many of the metropolitan workhouse medical officers have had to undertake an additional duty recently—namely, to visit once or twice a week, or when required, the new receiving homes for children, and that the salary added for these visits has been about £40 per annum

HASHEESH AS A CAUSE OF INSANITY AND CRIME

Dr John Warnock, medical director of the Egyptian Hospital for the Insane, Cairo records in the *Journal of Mental Science* for January last the results of his observations on "hasheesh," or cannabis indica, as an agency in the production of insanity and crime, drawn from an experience which is exceptionally large in this field of medicine. It is pointed out that Ibn Beitar, an Arabian physician, was the first to recognise an insanity from the use of hasheesh, A.D 1235 but the drug had then been in use probably for many centuries. At present the drug is largely consumed in Egypt, adds Dr Warnock, although its importation is prohibited by law The fact that about 16 tons of hasheesh were confiscated in Egypt during the year 1901 will give some indication of the extent of its use. "Most of the drug is consumed by smoking in the gozeh [an Egyptian pipe] and in cigarettes, but a considerable amount is eaten in pill form and in sweetmeats magoon, &c." The usual reason given by patients for using hasheesh is that it induces a general feeling of pleasure and content. When eaten in pills and sweetmeats it seems to be taken chiefly as an aphrodisiac Insanity from hasheesh belongs to the "toxic" group which includes insanities due to alcohol, opium, and cocaine. Dr Warnock classifies the insanities from hasheesh under the following types First there is the temporary intoxication from hasheesh which is attended with pleasurable exhilaration. Pleasant, half waking dreams not unlike those of the opium eater, occupy the mind, but active excitement as in alcoholic intoxication, is uncommon. Secondly there is a delirium from hasheesh, which is associated with hallucinations of sight, hearing taste, and smell. Great exaltation, restlessness, and sleeplessness are marked features, but there is an absence of the tremors and physical exhaustion of alcoholic delirium tremens The third variety is a more acute form of excitement attended with hallucinations, incoherence, destructiveness, indecency, and impulses towards violence Delusions of poisoning or of persecution are common in this affection. States of depression and terror may be intermingled with excitement. These cases tend to pass into a chronic condition which constitutes the fourth class Eventually there succeeds a

117 notified cases. The number of revaccinations increased from 156 in 1901 to 8688 in 1902, while the successful primary vaccinations increased from 1590 in 1901 to 2777 in 1902 As will be seen by a statement from our Dublin correspondent there are 16 cases of small pox in that city and on March 8th 1 patient died from the disease in the corporation isolation hospital.

ANNUAL DEBATE OF THE CHELSEA CLINICAL SOCIETY

THE members of the Chelsea Clinical Society commenced their annual clinical debate on March 10th at the Jenner Institute, Chelsea gardens, London, S W The subject was Diabetic and Non Diabetic Glycosuria and the debate was opened by Dr W Hale White, whose remarks will be found in full in this issue of THE LANCET, p 714 Dr Hale White was followed by Dr F W Pavy who in the course of his contribution to the discussion defined diabetes as "a more or less persistent defective assimilative action upon the carbohydrates of food resulting in glycosuria." A full report of the debate will be published in our next issue The two other speakers were Dr R. Saundby and Dr J Rose Bradford.

URÆMIC ULCERATION OF THE SKIN AND MUCOUS MEMBRANES

WE have recently in an annotation referred to the intestinal lesions of uræmia.[1] The cutaneous lesions of kidney disease resemble the intestinal ones in that they are also ill recognised and only in recent years have received attention. Erythematous, urticarial, papular, purpuric, and pustular eruptions have been described In connexion with a case of uræmic ulceration of the duodenum with hæmorrhage reported to the Société Médicale des Hôpitaux of Paris by M. Barié and M Delaunay (described in the annotation referred to), M P Dalché and M Henri Claude reported at the meeting of the society on Jan. 23rd an analogous and equally interesting case of hæmorrhagic ulceration of the skin and mucous membranes in uræmia. A woman, aged 36 years, was admitted to hospital Eight years before there was albuminuria during pregnancy which disappeared after labour During the next six years her health was fairly good. Then began headaches, gastro-intestinal troubles, and fugitive œdema of the legs and eyelids Dyspnœa, palpitation of the heart, and epistaxis appeared and three months before admission ecchymotic spots were observed on the limbs Hæmorrhages into the mouth, near the anus, and at the umbilicus followed in this order Hæmorrhage in the last position was present on admission The disease progressed rapidly and the patient died about a month after admission in a state of profound cachexia without having presented any acute symptoms of uremia, but cryoscopy showed progressive insufficiency of renal excretion. At the necropsy granular kidneys were found. M Dalché and M Claude laid emphasis on the characters of the hæmorrhages and ulcers which gave the case a special clinical aspect. On the limbs were purpuric spots and ecchymoses distributed almost symmetrically At the umbilicus and anus there was a slight oozing of blood the source of which was not evident. The saliva was constantly bloody and hæmorrhages occurred from the tongue and mucous membrane of the cheeks The tongue was yellowish white and at its sides were hypertrophied papillæ with fissures between them from which blood constantly oozed. A small hæmorrhagic ulcer and some purpuric spots were observed on the right side of the soft palate. On the mucous membrane of the cheeks two gangrenous patches appeared. Around the anus were small round ulcers with slightly elevated borders from which blood issued. In the week preceding death the buccal hæmorrhages became more and more abundant, the ulcers on the cheeks extended and became covered with a false membrane, the attempted removal of which increased the hæmorrhage. Ulceration gradually took place at the umbilicus, resulting in two bleeding ulcers of the size of a 50-centime piece with indurated and elevated borders In the last days of life they extended to the subcutaneous cellular tissue. In all the lesions the process seemed to be the same an extravasation of blood took place in the deeper layers of the skin or mucous membrane and was followed by destruction of the overlying tissues and hæmorrhage. The base of the ulcer had the characters of necrosis and not of inflammation. Histological examination confirmed this view, purely necrotic changes were found. Purpura is a well known manifestation of uræmia, but usually is not accompanied by hæmorrhage from the skin. M. Barié in 1889 described uræmic stomatitis, but in this affection the ulceration differed from that in the present case It was inflammatory and painful, the borders of the ulcers were not elevated, there was no hæmorrhage, and the tongue was not affected It is noteworthy that the ulcers occurred only on parts subject to friction—the tongue, mouth, umbilicus, and anus. In other parts, no doubt in consequence of the re-establishment of the circulation, the hæmorrhages were not followed by ulceration The cause of extravasation of blood in uræmia is doubtful. Amongst others alterations in blood pressure, in the vessels, and in the coagulability of the blood have been proposed. Schönemann has recently examined the mucous membrane of persons who died from uremia and had epistaxis. He found an increase in the number of the capillaries, which were so near the surface that some of them had perforated the basal membrane and insinuated themselves between the epithelial cells. Thus the capillary loops would be ruptured by the slightest injury In the present case the blood showed no loss of coagulability The necrotic lesions of uræmia described above show an interesting analogy with diabetes in which such lesions occur

STEAM TRAFFIC IN THE STREETS

IT is difficult of course to define sharply the difference between a motor car and a steam engine, but we are confident that the Locomotives on Highways Act of 1896 was never meant, at any rate in crowded cities, to license the running of a steam engine little short of the dimensions of a railway locomotive with a string of cars behind it through the streets Yet recently in certain thoroughfares in the West-end a steam engine drawing a number of cars, the whole train being much on the same scale as a goods train on the railway, has been a common spectacle Even down the narrow thoroughfare of the Strand at busy times of the day we have seen gigantic—there is no other word for it—steam boilers drawn along by a big powerful steam engine. The time surely has not come when our streets may be used with safety to the public as railroads. It seems to us to be placing a very elastic and audacious interpretation upon the meaning of the Act, which was intended for motor cars conveying persons in the same way as a carriage and not for heavy goods at all An accident occurred this week in which a coachman lost his life through the starting of a horse at the sight of one of these huge engines and its train of heavily loaded vehicles. If this engine and its cars are to be allowed the use of the streets without let or hindrance we may confidently expect further disaster The London County Council, by means of its by laws, should exercise the powers which it possesses in this matter We think that such traffic in the busy streets of London should be prohibited altogether of water really required for irrigation, washing or other purposes are treated once a week with kerosine oil for the destruction of larvæ (5) that the surface and rain water drainage of the premises is good and that the drains and roof-pipes are in proper repair (6) that the latrines are in good condition and well kept (7) that the drinking water is obtained and stored in a cleanly manner

---

[1] THE LANCET Feb 14th 1903 p 458

The school also intends to arrange courses of lectures on the prevention of tropical diseases, to be attended by clerks, missionaries, and others, both male and female, not in the medical profession, proceeding to West Africa and other tropical countries Each course will consist of five lectures extending over two weeks, in the months of January, May, and November Particulars may be obtained from the honorary secretary of the school, Mr A. H. Milne, B10, Exchange buildings, Liverpool.

THE DISTRIBUTION OF PLAGUE

As regards the Cape Colony the medical officer of health of the Colony states that for the week ending Feb 14th 5 cases of plague were discovered at Port Elizabeth, 1 being a European male, 1 a Malay male and 3 native males, 2 of the latter being found dead The cases were discovered on the following dates 2 on the 8th, 1 on the 9th, 1 on the 10th, and 1 on the 12th. At the end of the week 3 cases remained under treatment at the Plague Hospital, Port Elizabeth. Plague-infected rats continued to be found in the town of Port Elizabeth during the week. Also at Graff Reinet plague-infected rats and mice were found during the week ended Feb 14th. No case of plague has been discovered in any other place in the colony As regards Egypt the Director General of the Sanitary Department states that since Feb 6th no cases of or deaths from plague have occurred throughout Egypt The 3 cases that were under treatment have been discharged from hospital recovered.

THE PATHOLOGY OF GIGANTISM

IN the *Revue Neurologique* of Jan. 31st Dr P E Launois and Dr Pierre Roy give an account of the pathological observations made post mortem on the French giant, P—— K——, whose height was 2 12 metres (6 feet 11¼ inches), and who recently died from cerebral tumour in a hospital in Paris at the age of 36 years It is stated that at the age of 18 years he had nearly attained his full stature. An interesting discussion is given concerning the clinical features observed in this case and their correspondence with the post-mortem findings and the conclusion is reached that the gigantic stature in this case was due to acromegaly Thus in the year 1900 the patient showed distinct signs of this condition, the lower jaws being then abnormally enlarged and elongated, the tongue and nose being hypertrophied, and the hands appearing huge and spade-like. A marked degree of glycosuria developed at this stage, and at the same time he began to suffer much from præcordial pain, palpitation, and paroxysmal attacks like those of angina pectoris. As the glycosuria progressed emaciation set in, and a steadily progressing hebetude made itself manifest. Occasional epileptiform convulsions occurred which led to the suspicion of cerebral tumour and owing to the associated condition of acromegaly being present it was possible to diagnose the tumour as being one of the pituitary body The patient died during one of his fits and the necropsy revealed the following conditions. The cranial bones were much thickened and the sella turcica or pituitary fossa was found to be enlarged and occupied by a tumour of the size of a large Barcelona nut, measuring one and three-fifths of an inch transversely The growth extended into the right lateral ventricle of the brain and also projected forwards slightly between the fronto-orbital gyri. It was a primary epithelioma of the anterior lobe of the pituitary body, its outline was well defined, and although it pressed upon the brain substance it did not infiltrate the latter "The pituitary tumour," add Dr Launois and Dr Roy, "explains at once the gigantism, the acromegaly, and the diabetes." Another feature of interest was the enlarged thyroid gland which weighed 250 grammes or ten times the normal weight—a condition which has been termed "compensatory hypertrophy" and which has been regarded by most observers as in some way associated with the destruction of the pituitary body Such a hypertrophy of the thyroid has been noted in 13 out of 34 cases of acromegaly collected and published by Dr G Hinsdale of New York in 1898 There was also in the present case evidence of tuberculosis at the apex of the left lung Dilatation of the sella turcica had been noticed in the skulls of giants by Tartuffi in 1877, and in a memoir on the skull and skeleton of the Irish giant MacGrath Professor D J Cunningham pointed out (1891) that a similar condition was present and that the bones also showed evidences of acromegaly Gigantism and acromegaly are now known to be closely related conditions, and Dr. Launois and Dr Roy conclude that they are both phases of a morbid process of bodily nutrition due to a lesion of the pituitary body

DREAM-FAITH

THE recent sad case of drowning at Shanklin with the sensational evidence given at the inquest by a fisherman's wife who found the corpse, will be treasured with avidity no doubt by large numbers of persons. Amongst all classes there are to be found plenty of individuals who 'believe in dreams" and a larger number still who, though not prepared to affirm their actual belief, yet think that probably there is "something in them" These people hold in fact, that mere coincidence will not account for such occurrences as that to which we are referring It will be remembered that the body of the unfortunate Miss Lumsden was found upon the rocks by a woman who stated at the inquest that she was led to search this spot by having on three successive nights dreamed that she saw there the corpse of the missing lady Such a statement is at once enough to convince the believer in dreams. It fulfils at a breath all his hopes and carries out to the full visionary aspirations which perhaps he has approached hitherto but has never seen definitely realised To such people it would be vain to ask how many other fishermen s wives in and about Shanklin dreamed of the unhappy lady lying cold and dead upon the rocks Scientific investigation of the foundation of their creed is not for dream believers, and though in a hundred cases the same dream were to occur—as it probably did in this instance—to different people the ninety nine where it proves false are ignored in the jubilant acceptance of the one case where the dream coincided with the facts. Generally speaking, indeed, the enormous numbers of dreams the thousands nightly that never, so to speak, ' come off, are entirely disregarded in the presence of the one that hits off the facts —or at any rate appears to do so afterwards. For with all the honesty in the world the imagination of a poor woman dwelling by the sea, fostered as are the imaginations of a sea shore folk by the winds and waves and suggestive sights and sounds of the waters, is flexible to the extreme and readily takes for true what suits its natural trend. The very number of times that the dream occurred is suggestive. Three is the favoured numeral of the superstitious and we can quite believe that if this fisherwife had but dreamed her dream on two occasions, or a night or two apart, these would have welded themselves in her imagination into three successive nights. The natural desire of humanity for communication with the supernatural has been a feature of the human race ever since the earliest times of which we have any record.

condition of permanent dementia with loss of memory, apathy, and degraded (wet and dirty) habits, a state of terminal dementia which ends in death. A fifth class includes 'degenerates" in whom there arise periodically strong cravings for hasheesh. Persons of this class, adds Dr Warnock, are "good for nothing, lazy fellows, who live by begging and stealing, the moral degradation of these cases is their most salient symptom. While in the asylum they are notorious for making false charges, refusing to work, and quarrelling Irritability, unconcern as to the future, malingering, and fervent promises of reform are all marks of this state." The craving for the drug in this affection is not so great as in dipsomania or morphinomania In the earlier stages such persons usually commit crimes and find themselves in gaol Later, when intellectual impairment becomes more marked, they are sent to an asylum. The similarity between this condition and that of dipsomania, adds Dr Warnock, is evident, while many of the differences are probably due to racial peculiarities. Suicidal attempts in insanity due to hasheesh are rare. The drug, however, appears, concludes Dr Warnock, to play a more important part in the production of insanity in Egypt than alcoholism in England, while as a cause of crime it appears to be as important in Egypt as alcoholic excess is in England.

THE ROYAL COMMISSION ON LONDON TRAFFIC

WITH the institution of a Royal Commission there is at least the beginning of a prospect that the streets of London may in the future provide something more than a notable example of the judicious exercise of police authority There is no more striking object for the foreign visitor to London than the policeman's outstretched arm—a silent symbol of recognised authority behind which are halted a score of patient omnibus teams which doubtless would, if they could, sympathise with the smothered imprecations of their own and neighbouring drivers The management of London road traffic by the London policeman is no doubt a fine spectacle, but no one will be sorry to see the difficulties removed, however eloquent a testimony to national character may be the manner in which those difficulties are at present met. We call the London policeman in face of London traffic a testimony to national character because no less conservative nation would have tolerated so long the overcrowded condition of London thoroughfares, nor, having such a state of affairs actually to deal with, would the police force of any other nation be able to control the situation with such equanimity and good nature —a good humoured acquiescence in accepting inconvenience common to the authorities and to those whom they control. The large number of street accidents in the metropolitan areas bears a close relation, there can be little doubt, to this condition of congested traffic We have many times attempted to stir the municipal authorities to a keener sense of the inadequacy of existing arrangements for the provision of first aid and of ambulances for the unfortunate victims of street accidents It will be a more drastic remedy than any such improved provision if future arrangements can actually diminish accidents instead of merely disposing of them more conveniently We shall be more content to endure our present ambulance arrangements, improving as they at least are, if a future system of underground railways, of wide streets, and of better division of traffic renders street accidents materially fewer Up to now the Central London Railway has been remarkably safe so far as injury to life and limb is concerned and in proportion as more traffic is diverted from the roads to the railways it is to be hoped that a greater safety will prevail among the travelling public in London. 'Motor" traffic is as yet an almost negligible factor on London roads It may fairly be anticipated that this will not be so within a very few years and that the Commission will consider the possibility of such a change. How far the substitution for horse power of electric and petrol engines will increase the public safety we cannot yet fairly judge. Electric shock mishaps have occurred with some frequency, it is true, yet they are fewer probably than is imagined, their somewhat sensational and novel nature leading every such incident to be recorded prominently and consequently to be impressed upon the public mind with an *éclat*, so to speak, that is not accorded to the mere victim of a runaway horse or of an overturned hansom We are presuming that underground railways and public motor cars will be a feature in the traffic arrangements of the future, but even if these innovations are delayed there is scope for much improvement in the regulation of London traffic. The Embankment is a wide road but it is not sufficiently employed, the river provides a melancholy spectacle of deficient enterprise, the omnibus is a cumbrous if useful vehicle that takes up far too much room, and cab traffic might well go through Hyde Park within certain hours When ideas such as these so readily suggest improvements to the interested spectator of London roads day by day it may well be hoped that extensive improvements may be evolved from the combined intelligences of a well chosen Royal Commission. We look forward to the day when a journey from Hyde Park Corner to the Strand, let us say, will be less than half occupied by waiting in the confines of various "blocks."

LIVERPOOL SCHOOL OF TROPICAL MEDICINE

IN accordance with the advice of Sir William McGregor, K.C.M.G. C.B., M.D., Governor of Lagos, West Africa, the Liverpool School of Tropical Medicine has drawn up a set of simple instructions for the prevention of malaria, primarily intended for the guidance of Europeans living in malarial or tropical countries and in the employment of British mercantile firms These instructions contain the results of the most recent observation and experience on the subject and they deserve the careful attention of all residents in malarial districts The opening paragraphs explain that malaria is contracted only from the bite of the anopheles, that black water fever occurs only in those who have suffered periodically from malaria, and that complete protection may be secured by observing certain precautions which, as above mentioned, are put in the form of regulations to be carried out on the premises of a mercantile house and relate to the use of mosquito nets and wire gauze screens, the taking of quinine, and the supervision of all collections of water

1 *Mosquito nets*—The senior should satisfy himself that all the European employes of the firm invariably sleep within mosquito curtains of a mesh of not less than 10 holes to the inch and kept free from rents. Rents are most easily mended by twisting up the net at the point of breakage and tying round with a piece of string The net should when in use be hung inside the poles and tucked in under the mattress When not in use the free sides of the net should be drawn together twisted somewhat and thrown across the top of the net. The net should not have a slit or join in the side. A mosquito is never found inside a properly used net It is wise to tack on a piece of material all around the net, above the level of the mattress so as to protect the limbs from bites through the net during sleep Mosquito boots to protect the ankles in the evenings may also be recommended

2 *Quinine*—All the European employes of the firm should take at least 15 grains of quinine per week and should report in writing to the senior that they are doing so

3 *Mosquito-proof room*—The senior should see that the quarters provided by the firm for their European employés possess at least one sitting room or portion of a verandah securely protected by screens of wire gauze against the entry of mosquitoes The room or portion of verandah selected for protection should be that which is commonly used by the inmates from sunset to bedtime

4 *Punkahs*—The senior should see that the office of the firm and the common dining room of the European employés are provided with punkahs or electric fans to be used during office hours and during meals respectively

5. *Details.*—The senior should see (1) that the premises of the firm are provided with at least one rubbish bin (with a cover) (2) that all cisterns tanks tubs and other vessels required for the permanent storage of water are furnished with accurately fitting covers and also with wire-gauze caps to the pipes for the purpose of excluding mosquitoes (3) that all useless pits pools tanks, disused wells and other unnecessary collections of water within the premises of the firm are filled up or drained away (4) that al open and permanent collections

to Thebes. Gout, rheumatism, and hydrophobia (before unknown) have become common of late years" Now that so many English people visit the Egyptian capital every year (to say nothing of the British colony, as it is called locally) it would be useful to inquire whether in reality the Cairene climate is less salubrious now than it was before the water company was established and gardens became common in the suburbs of the ancient city Formerly the only place where verdure was to be seen was at the Hôtel du Nil, off the Mouski. Then the Esbekieh gardens were created by Ismail Pasha, and soon afterwards gardens sprang into existence wherever there was room for them but especially in the new Ismailiyah quarter Two at least of the diseases mentioned by Sir Richard Burton are not commonly supposed to be due to excessive moisture, but there are no doubt complaints which increase in virulence, even if they do not originate *de novo*, when land hitherto arid and undisturbed has been subjected to the influence of irrigation. In Dr Engel Bey's latest publication dealing with meteorological subjects[1] the head of the statistical branch of the Egyptian sanitary department inclines to the belief that the climate of the Delta has undergone some modification in consequence of the "regularisation of the waters of the Nile' under English engineers. But before he can pronounce a definitive opinion on this question he says, in conclusion, it will be necessary to wait until a longer series of observations becomes available. So far the fringe of this interesting subject alone has been looked at, but so great is its importance to the country that in his opinion it urgently demands an exhaustive examination.

A PERNICIOUS HABIT

ON the labels of some boxes of cigarettes at present being sold to the public is a statement to the effect that the cigarettes are made of the purest tobacco and paper obtainable and that, therefore, the smoke from them may be inhaled safely and without irritating the respiratory passages. We do not hesitate to say that such a statement is highly mischievous and that the practice of inhaling smoke into the lungs is attended with considerable risk to the health of the smoker It is to be feared that the cigarette is responsible largely for the prevalence of this objectionable habit of inhaling tobacco smoke, the pipe- or cigar smoker is as a rule not addicted to it because probably the smoke is too strong or too irritating But the fact that the smoke of a cigarette may be unirritating does not minimise the evil effect of drawing the smoke into the lungs, for by this method the absorption of the poisonous constituents of tobacco smoke (and all tobacco smoke is more or less poisonous) is very rapid, these entering quickly into the circulatory system by way of the pulmonary capillaries Even in the mouth and nasal passages there is some amount of absorption, but this is trifling compared with that which takes place in the lungs. The practice of inhaling tobacco smoke is therefore strongly to be discountenanced and vendors of cigarettes should refrain from printing on the boxes mischievous statements such as that to which we have alluded. There is no reason for believing that smoking tobacco in a rational way is productive of harm, on the contrary, it is the common experience that when moderately indulged in it serves to allay restlessness and irritability, but the sequelæ to the habit of inhalation may indeed be dire, the heart and nervous system being chiefly affected. Yet many cigarette-smokers inhale the smoke into the lungs as may be seen from the fact that very little of the smoke which they draw from the cigarette is afterwards ejected. In the same way the smoke from the burning end of a cigarette from its close proximity to the nose is sometimes taken into the lungs, occasionally producing stupefying effects

THE WEIGHT OF EVIDENCE

IN THE LANCET of Jan 31st, p 344 we published under the heading, "The Risks of Medical Practice," a note upon a case heard at the January quarter sessions held at Margate The case was one in which a medical practitioner, William Herbert Ray, had been sentenced to six months' hard labour for unlawfully assaulting a girl The only evidence against the medical man was apparently that of the prosecutrix herself and we considered that it "opens up a dangerous vista if any medical practitioner can be convicted of outrageous conduct on the unsupported word of a patient.' A report of a somewhat similar case is before us in which a Guernsey journalist named Percy Edward Amy was sentenced at Guernsey on Feb 18th to ten years penal servitude on the mainly uncorroborated evidence of a girl. The charge, according to the evidence of the complainant was that on the evening of Jan 18th Amy enticed or persuaded her to go to his room at the office of the *Guernsey Evening Press* and there by saying that he could lock her up (she had been discharged on suspicion of dishonesty from her last place) and by saying that he would chloroform her persuaded her to undress He undressed himself and then whipped complainant with a cord or strap He then, we gather from the report of the trial in the *Guernsey Evening Press* of Feb 18th, raped her After this the complainant and the prisoner walked to church together Next morning she told her mother all that had happened. The medical evidence bore out the girl's story as to the whipping but, according to the report, there does not seem to have been evidence given as to the rape. For these reasons and considering that the jury only found the prisoner guilty by seven votes to four, we consider that the sentence should be revised. In Mr Ray's case, too, we consider that as the evidence of the girl was totally uncorroborated there is every ground for a revision of his sentence as well.

THE EFFECTS OF BORIC ACID AS AN INTERNAL MEDICINE

DR. G MERKEL of Nuremberg has published in the *Münchener Medicinische Wochenschrift* of Jan. 26th, an article dealing with the effects of boric acid as an internal medicine He also refers to the injurious effects of this drug when used as a food preservative, especially when such preserved food is given to invalids Attention was called to this subject some time ago when an annotation on the subject of cases of boric acid poisoning was published in THE LANCET of Nov 30th, 1901, p 1514, based upon the observations of Rinehart. Dr Merkel states that boric acid taken internally in medicinal doses produces irritation of the gastro-intestinal tract. His conclusions are based upon observations made on 11 patients suffering from various slight ailments, but in whom the gastro intestinal tract was normal. Boric acid was given in doses of from one to two grammes daily in aqueous solution. The longest period of administration was eight days and the shortest was two days In seven of the 11 patients disturbance of the gastro-intestinal tract commenced shortly after taking the drug The chief symptoms were formation of gas in the stomach and intestines, eructations, colic, pain in the epigastrium, and diarrhœa. As the patients were free from gastro-intestinal trouble before taking the boric acid the characteristic troubles which followed were, it is urged, undoubtedly due to the drug The use of this drug therefore, concludes Dr Merkel, is contra indicated in the case of invalids or persons in delicate health It should not, he thinks, be used as a preservative for milk and

[1] Le Climat du Caire et d Alexandrie Cairo 1895

Such desire, unless safeguarded by some definite religious organisation, always leads to the wildest and most foolish superstitions We cannot wonder at uneducated persons believing in portents, in the malign influence supposed to be exercised by a comet, in ill luck and similar superstitions, when we find persons of education and men of the world apparently seriously guiding their life's course of action by means of warnings given through the medium of a piece of wood, a penny lead pencil, two pantograph wheels, and a piece of paper

THE SANITARY INSTITUTE

THE twenty first congress of the Sanitary Institute will be held at Bradford on July 7th to 11th, 1903, the Earl of Stamford being President The section of Sanitary Science and Preventive Medicine will be presided over by Professor T Clifford Allbutt, the section of Engineering and Architecture will be presided over by Mr Maurice Fitzmaurice, C M.G, M. Inst. C E, and the section of Physics, Chemistry, and Biology will be presided over by Professor C Hunter Stewart The usual popular lecture will be given by Mr J Slater, B A., F R I B A. Eight technical conferences will also be held in connexion with the congress, presided over by Mr W C Lupton, Professor Thomas Oliver, Dr J Spottiswoode Cameron, medical officer of health of Leeds, Mr T H Yabbicom, M. Inst C E Mr C Drabble, M R C V S, Mrs Moser, Dr James Kerr, medical officer to the London School Board, and Mr Isaac Young

WORKHOUSE MEDICAL OFFICERS AND REFRACTORY PAUPERS

A CORRESPONDENT addresses us as follows —

> I shall be greatly obliged if you could give me advice on the following A is medical officer for the workhouse and district but not police surgeon B is a pauper in the union a rowdy fellow with a bad heart who is periodically handed over to the police for assault &c., in the house One night lately he was arrested there and taken to the police-station After a time the officer on duty thought him ill and sent to the union to have the medical officer of the workhouse sent to see B in the cells A constable accompanied the messenger from the union to A's house As A has had some difficulty before with the police staff over similar matters he replied that B having been arrested and taken to the cells he was now out of his (A's) care as a pauper and that either they must send for the police surgeon or send him (A) a proper request from the police station not under cover of the workhouse A sat up till 1 A.M (the message came at 11 P.M) but no further communication came till yesterday when A got a letter from his board of guardians asking him to explain his refusal to attend unless the police paid him and enclosing a long letter to the guardians from the superintendent of police making the above accusation and asking for payment of 8s 6d, the police surgeon's fees for attending the case
>
> Was A justified in his line of action? or was he still responsible for the treatment of B? If so is he liable to be sent for to attend every drunken rowdy in charge who *may* be a pauper even without a relieving officer's note?

If the circumstances mentioned in the above letter include all the facts bearing on the incident and neither correction nor amplification be required, then it appears to us that our correspondent was legally justified in his line of action Two offices are held by him—one at the workhouse the other in the district Article 207 of the general consolidated order deals with the former of these appointments and states that the duty of the medical officer is "to attend *at the workhouse* at the periods fixed by the guardians and also when sent for by the master or matron" Clause 2 of the same article states that the medical officer shall "attend duly and punctually upon all poor persons *in the workhouse* requiring medical attendance" (The italics are ours.) There is no clause in the article quoted, nor can we find one elsewhere, which would enable the guardians or the master to call upon the medical officer of the workhouse to visit and to attend a person who had left the workhouse In connexion with this point it may be mentioned that it is within our knowledge that stipendiary magistrates on many occasions when refractory paupers were charged before them have asked the respective workhouse medical officers to examine the prisoners in the cells and that in each instance, so far as can be ascertained, a fee of 10s 6d was awarded. Evidently the magistrates were convinced that workhouse medical officers were entitled to remuneration for examining paupers at police-courts The obligations affecting the holder of the post of district medical officer may be read in Article 206 of the same consolidated order Briefly they are "To attend duly and punctually upon all poor persons requiring medical attendance within the district assigned to him whenever he may be lawfully required to furnish such attendance by a written or printed order of the guardians, of a relieving officer, or of an overseer" The two extracts from the consolidated order define the position clearly enough. The police have no legal basis upon which they can demand the attendance of the parish medical officer, as parish medical officer, upon a pauper in their custody There is a person expressly appointed for the purpose—namely, the police surgeon. Our correspondent must remember that it will be his duty under Article 205 to give to the guardians all the information that he is able to supply respecting the case. Whether it will be wise for him always to adopt the line of action legally justified is a matter for his consideration.

SUTURE OF THE PATELLA

M QUÉNU of Paris (as reported by our correspondent) has recently been making some researches into the strength of the union effected by suturing a fractured patella He has shown in the dead body that if a patella is united by a wire suture by any method a comparatively small weight can cause some separation of the fragments. We should think that the separation was probably due to stretching of the wire or to partial untwisting of the "knot." That weights of 100 and 150 pounds could give rise to an interval of a quarter of an inch between the fragments does not affect at all the question of the value of suturing fractured patellæ. The object of the wire is not to hold the fragments together while a force of 100 pounds or more is applied, but it is intended to resist the pull of the quadriceps muscle and to maintain the fragments in the best position for the formation of osseous union. On no account should the suture be relied on to withstand voluntary movements of the limb Thus M Quénu's experimental results, though of interest, are of but little practical importance, for no surgeon trusts to wire for permanently holding the fragments together The full time for bony union should be allowed to elapse before the patient is permitted to bear any of his weight on the affected limb Used in this way suturing is probably the best treatment for a fractured patella, but even without operation good results may be obtained if sufficient care be taken to bring the fractured surfaces into apposition. In the present issue of THE LANCET Mr G T Mockett of Burslem describes a method he employs which is ingenious. The chief point in his method is the employment of a sheet of lead with a hole in it just large enough to contain the patella. This is applied over the knee and thus the fractured surfaces are maintained in contact, strapping and bandages being also employed to fix the fragments.

THE CLIMATE OF CAIRO

IN a footnote on p 182 of his "Thousand Nights and a Night" (Library Edition) the late Sir Richard Burton gives it as his opinion that of late years the climate of Cairo has deteriorated. "Even as late as 1852," he says, "when I first saw Cairo, the city was girt by waste lands and the climate was excellent Now cultivation comes up to the house walls, while the Mahmudiyah Canal, the planting the streets with avenues, and over watering have seriously injured it, those who want the air of former Cairo must go came out as 1 to 922. In his opinion accessibility was the most important consideration in the selection of a site for a great general hospital. In the fourth district, where there was only one bed to every 1877 people, equally satisfactory results would have been presented if South London had exhibited the same interest in hospitals and the same desire to provide the population residing therein with hospitals as had been manifested by other districts of the metropolis. His own view was that habit governed such questions to a very great extent and the people of South London had grown up in the habit of relying upon Guy's Hospital for at least two centuries to provide them with hospital accommodation and because Guy's Hospital was an endowed institution they had never felt the need or realised the duty of contributing their share of the expenditure entailed by the upkeep of hospital beds for the accommodation of the population residing within their borders. There was evidence to show in District No 5 that the growth in population of a place like Tottenham, where the London County Council is moving from the congested parts of London to that district upwards of 40,000 people, should render the authorities fully alive to the necessity of providing additional hospital beds. He hoped that the Tottenham Hospital authorities would continue to press the London County Council and that as a result of such action a scheme might be possible whereby the County Council would consent to provide the money necessary to build additional wards upon the excellent site which the Tottenham Hospital authorities possessed to meet the hospital requirements of the population they were settling in Tottenham. The money to build such wards could be provided with a sinking fund and in any case two things should be secured in any such settlement. First, the enlarged hospital should be left under the management of the committee elected by the governors of the Tottenham Hospital and, second, the additional revenue for the maintenance of the new beds, provided for what may be termed the County Council population should be forthcoming through the free offerings of the new residents in the district whose requirements they are supplied to meet. He was aware that the London County Council had not at present any Parliamentary power vested in it to devote money to the erection of a pavilion or pavilions in connexion with the Tottenham Hospital to provide beds for the hospital requirements of the 40,000 people whom the County Council was about to move into the district of Tottenham. But he felt that the attitude assumed towards the housing question by the present members of the London County Council entitled the citizens to expect at their hands an intelligent recognition of the responsibilities which devolved upon them in regard to such wholesale removals into a particular district as those provided for under the Tottenham scheme. He put it to the London County Council and through them to the citizens of London. Was it right for the municipality to plant a population of over 40 000 souls in an outlying district of the metropolis without making any provision whatever for the hospital accommodation of the people who had been removed from centres where they could readily obtain such relief to a new centre where the existing population had already provided themselves with a reasonable amount of hospital beds, none of which could be made available for the newcomers introduced by the London County Council? This consideration led him to repeat that he hoped that the London County Council would seek the necessary powers and insure the provision of an adequate number of hospital beds in connexion with the Tottenham Hospital for the new population it was bringing into this district. Sir Henry Burdett continuing turned to the question of the removal of certain large hospitals in London to new sites in relatively congested districts. The districts in which the population was congested and which were without adequate hospital accommodation were practically three, South London Battersea, and Tottenham. Tottenham he had dealt with and there were left South London and Battersea. South London was said to be in negotiation with the King's College Hospital for the removal of that institution to Camberwell. That would leave Deptford, Greenwich and Woolwich unprovided for except by the Miller and the "Dreadnought" Seamen's Hospital. He suggested that the Miller Hospital might unite with the North West London Hospital, in which case a new site must be found. In regard to Wandsworth and Battersea there was the Bolingbroke Hospital but the ratio of beds was as 1 to 13,364 and the position should excite the sympathy of the wealthy and secure for the residents an adequate hospital. In regard to which of the large hospitals might be transferred to new sites it seemed to him that King's College Hospital might be moved and also Westminster Hospital. There was, in his opinion, no urgent demand for the removal of St. George's Hospital. With reference to Westminster Hospital he thought it could be moved to Wandsworth and amalgamated with the Bolingbroke Hospital. The speaker then observed that he had said nothing so far in regard to a hospital, St Bartholomew's, which had been much in evidence of late. St Bartholomew's was the only general hospital situated within the City boundaries and he could not conceive the City of London ever consenting to permit so representative an institution with eight centuries of history to be removed from its present site to any site except one which was closely adjacent to, or only just outside, the City boundaries. Such a site had been mentioned in St Luke's, but there were very serious financial and other difficulties involved, and he did not think that the question was ripe for public discussion nor could it be so discussed with advantage until the governors of St Bartholomew's Hospital, who were trustees for the estates of that institution, had looked at the financial aspects of the two sites from every point of view and, as men of business, had recorded and published their decision thereon. In regard to the removal of large hospitals from cities to the country the proposal seemed to him to be impracticable if due regard was to be paid to the interests of the patients and the circumstances which affected city populations and the great hospitals which ministered to their needs. Formerly convalescent institutions were buildings to which patients were admitted when their wounds were healed and they had arrived at that stage where disease had ceased and health had to be restored. To-day many of these so-called convalescent institutions were largely utilised by residents in towns who needed fresh air and rest and who were not really in the medical sense acutely ill or frequently suffering except from general debility due to want of fresh air and change. That circumstance had no doubt led to a new departure so far as the London hospitals were concerned. Several of the general hospitals now had convalescent hospitals of their own situated in the country to which they could send suitable cases with unhealed wounds to the great advantage of the patients. In his judgment that represented the best form in which large hospitals could keep their patients in touch with the country without incurring grave risks of adding to the sufferings and anxieties of the sick and their families in large centres of the population. It was most desirable that some reconsideration should take place in regard to the system of admitting patients to several of the great hospitals of London at the present time. The enormous growth in the number of surgical cases now admitted and of the operations which were performed, coupled with the important developments in methods of treatment, had tended to cause those who regulated the admission of in patients to give so much preference to acute and surgical cases that very many patients suffering from relatively chronic affections which used formerly to be found in hospital wards were now relegated in increasing numbers to the Poor law infirmary. He was inclined to think, having regard to the necessities of medical education and the claims of the suffering poor, that the present system of admitting patients to our hospitals must be reconsidered. In any case the time had arrived when the Poor law infirmaries, in the interests of the patients they contained, should be thrown open to medical instruction. In conclusion Sir Henry Burdett pointed out that with the exception of Wandsworth and Battersea, where the ratio of general beds to population was as one to every 13,364 people, and the district including Deptford where there was not a single hospital bed for upwards of 110 000 people, the population within the whole of the postal districts of London was in fact, well supplied with general hospital beds. Indeed, if they added to these beds the beds in special hospitals then every district, with the two exceptions just mentioned, showed that the ratio of all hospital beds to population was infinitely greater than that laid down by the accepted authorities as a basis for calculation—namely one hospital bed for every 1000 people in a given district. If, therefore, King's College Hospital removed to a site situated conveniently for the population of Deptford if the North-West London Hospital united its forces with the Miller Hospital and erected modern buildings on a site convenient for the residents in Greenwich Lewisham and Woolwich, and if the Westminster Hospital moved the question of hospital sites and population in London would be placed "canned" foods. Food "preserved' with it may be taken sparingly by healthy persons, but such food should never be given, in his opinion, to invalids

DINNER OF THE MEDICAL SOCIETY OF LONDON

THE 130th anniversary dinner of the Medical Society of London was held on March 7th at the Whitehall Rooms, Hôtel Métropole, Mr A. Pearce Gould, the President, being in the chair 176 Fellows and guests sat down to dinner, among the latter being the Lord Chancellor, Lord Sandhurst, the President of the Royal College of Physicians of London, and the Presidents of the Royal Medical and Chirurgical Society the Clinical Society and other learned societies After the usual loyal toasts "The Medical Society of London" was proposed by Sir William S Church, Bart., K.C B, who drew attention to the broad basis upon which the society had been founded by 30 physicians, 30 surgeons, and 30 apothecaries. The President replied. The toast of "The Guests" was proposed in a humorous speech by Sir Frederick Treves, Bart, C B, K.C V O, who mentioned the fact that long before the rest cure had been adopted by the medical profession it had been instituted under the ægis of the legal profession at Portland where the sea air and the regular hours and meals had promoted the health of the convicts The Lord Chancellor, in reply, mentioned that the medical and the legal professions had this in common that they both worked for the corporate welfare of the community The Hon R. P Porter, U S A., also replied for the guests and mentioned incidentally that the Medical Society had "started in business" before the United States of America, having been instituted in 1773 The toast of ' The President" was proposed by Sir Richard Douglas Powell, Bart, K.C V O, and Lord Sandhurst, in seconding, said that he wished to take the opportunity of paying a tribute to the devoted services which had been rendered by the medical profession in stamping out the plague in Bombay at the time when he was Governor Music and songs were contributed by Mr T G A Burns, Dr F G McCann, and Dr S Henning Belfrage The gathering was universally voted to be one of the most successful of those which have been held by this ancient society

COUNTRY HOLIDAYS FOR LONDON FEMALE WORKERS

THERE can be no doubt that an annual holiday is a physical and mental necessity for all who work and sleep amid the noises and distractions of a great city, to say nothing of the dust and smoke which are always present in the atmosphere of London, but the poorer workers in the metropolis are but seldom able to avail themselves of the benefits of the pure air of the country The Factory Girls' Country Holiday Fund was started some 15 years ago in the interest of girls who live and work in the neighbourhood of Saffron hill, London During the first year of the existence of the fund 38 workers were enabled to take a holiday, since then the work of the fund has grown year by year, until in 1902 no fewer than 3200 girls and women were sent to the country from all parts of London. This is a record of which the workers for the fund may well be proud, but the financial committee reports a deficit of £38, which we sincerely hope will be speedily cleared off when the matter is brought before the notice of the charitable public. As it is not possible to delay the payments for board, lodging, and railway fares the strain upon the finances of the fund is very great, especially as donations and subscriptions flow into the coffers of the fund slowly The Factory Girls' Country Holiday Fund is an unassuming and very valuable charity but the present times are hard for all charities Expenses generally are increasing, there is an oppressive income tax, while the rates rise with undeviating regularity, the London County Council having just announced an increase in its rate of 1¼*d* Nevertheless, there are many charities the operations of which might well be curtailed before those of the charity the claims of which we are now advocating Subscriptions and donations should be sent to the chairman of the committee, St. Peter's Rectory, Saffron hill, London, E.C., to the honorary treasurer at the same address, or to the London and Westminster Bank, Holborn Circus Branch, E.C

THE annual festival dinner of the Irish Medical Schools' and Graduates' Association will take place on St. Patrick's Day, March 17th, at 7 30 P M, at the Café Monico, Piccadilly circus, London, W Application for tickets should be made to Mr Charles Ryall, 51, Queen Anne-street, W

THE following gentlemen have been appointed Knights of Grace of the Order of St. John of Jerusalem in England — Surgeon Lieutenant-Colonel Matthew Baines, V.D (from Honorary Associate), Mr Reginald Harrison, F R.C S Eng, and Dr F M Sandwith (from Honorary Associate)

The annual general meeting of the members of the Medical Graduates' College and Polyclinic is to be held on Tuesday, March 31st at 5 30 P M, when Sir William H. Broadbent, Bart., will take the chair

THE laboratory meeting of the Pathological Society of London announced to be held at the Examination Hall, Thames Embankment, on Tuesday next, March 17th, will not be held.

Sir John Williams, Bart., who has retired from practice, is leaving London next week to take up his permanent residence in Wales.

THE HOSPITAL PROBLEM IN LONDON

AT a meeting of the Hospitals Association at Caxton Hall, Westminster, London, S W, on March 3rd, Sir TREVOR LAWRENCE (treasurer of St Bartholomew's Hospital) took the chair There was a full attendance to hear an address by Sir Henry Burdett, entitled "Hospital Sites and Population in London" The speaker discussed the problem as to whether any, and, if so, which, of the large hospitals ought to be moved from their present sites to new ones situated in congested districts or in the country

Sir HENRY BURDETT said that the best way of dealing with the facts briefly was to take the City of London as a centre and then to divide the area round into five districts. District No 1 comprised the City of London alone, and the ratio of beds to population in 1901 was in the proportion of 1 to 40 District No 2 comprised Stepney, Shoreditch, Finsbury, Holborn, City of Westminster, Southwark, and Bermondsey, with a ratio of beds to population of 1 to 418. The third district was composed of Poplar, Bethnal Green, Hackney, Islington, St. Pancras, St. Marylebone, Kensington, Paddington Chelsea, Battersea, Lambeth, Camberwell, and Deptford, with a ratio of beds to population of 1 to 1054 District No 4 included Stoke Newington, Hampstead, Fulham, Wandsworth, Lewisham, Greenwich and Woolwich, with a ratio of beds to population of 1 to 1877 The fifth district was in four home counties and was well outside the metropolitan boundary, but part of it was in the County of London. It included Essex (West Ham and Romford), Middlesex (Tottenham and Edmonton, Barnet, Hendon, and Brentford), Surrey (Croydon, Kingston and Richmond), and Kent (Bromley and Dartford) Here the population had increased nearly 93½ per cent. and the ratio of beds to population was 1 to 2482. The usual estimate in regard to hospital beds in general hospitals in relation to the needs of the population was as 1 to 1000 people and dealing with the five districts enumerated as a whole the ratio been relieved during the year from the ordinary income of the charity fund and 31 patients had been relieved by the Bevan Trust fund

In the absence of Dr T S Clouston through indisposition the report of the physician-superintendent was read by Dr J M. Rutherford, Dr Clouston's principal assistant. The total number of patients under treatment during the year had been 1385 There had been 423 admissions, of whom 189 were men and 234 were women. The number of patients discharged had been 297, of whom 130 were men and 167 were women. There had been 138 deaths, of whom 73 were men and 65 were women The number of rate-paid patients admitted was 358, which was eight more than the average of the past five years In consequence of the large number of pauper patients sent in, the wards of the West House had been in a chronic condition of overcrowding such as he (Dr Clouston) had never before experienced It was a state of matters which was bad for the discipline and quiet of the wards, as well as for the health of the patients

As to the cause of insanity in the cases admitted no fewer than 119 cases, or 28 per cent of the admissions, were put down as due to intemperance in the use of alcohol. This was the highest number that had ever been sent there from that cause. Of the 423 admissions 56, or 13 per cent., were cases of general paralysis. This was, with the exception of last year, the largest number of cases of this disease that had ever been sent in and this confirmed his remarks in his last year's report as to the distinct increase of this disease in this district Their admission rate in this disease was now the highest in Scotland Of the 297 patients discharged 134 were recovered. One-third of the admissions were incurable from the beginning, being cases of advanced senility and gross brain lesions The number of deaths had been the largest that had ever occurred in the institution and the death rate was also somewhat larger than they had ever experienced. The causes of the high mortality were (1) the large number of cases of general paralysis, organic brain diseases senility, and general weakness, (2) the overcrowding of the wards, and (3) an outbreak of asylum dysentery or colitis. This epidemic occurred among the female patients There were 27 cases in all with seven deaths Only three of the patients attacked were however, in fair bodily health at the time, 18 of the cases having occurred in the female hospital of the West House and six in No 1 female ward where the patients were of a class weak in body

The drainage system of the West House had been thoroughly renovated four years ago, but part of the old system had at that time been left for the purpose of draining some deep cellars. After the epidemic of dysentery began it was found that some of those old drains had not been properly disconnected from the building and were undoubtedly dangerous Two of the cats in the ward had contracted the disease and had possibly acted as carriers of infection. When this was discovered the cat life of the institution came to an abrupt termination. Dr Clouston, in concluding his report, referred to the treatment of incipient cases of insanity in the wards of a general hospital. He believed that it would be a humane and perfectly practical proceeding if such a step were taken by the Royal Infirmary

THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS

CORK

As already mentioned in detail by our Cork correspondent in THE LANCET of March 7th, p 690, the preliminary steps have been taken for the formation in that city of a branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. The meeting convened for the purpose was attended by a number of influential persons the Church the medical profession, the county families, and various public bodies being represented

WINSLEY SANATORIUM

Progress is being made with the scheme for the erection of a sanatorium at Winsley, near Bath, for the counties of Wilts Somerset, and Gloucester The site, on high ground overlooking the Avon valley, has been levelled and tenders are being invited for the erection of the buildings Liberal contributions to the fund that is being raised have been received from the men employed at the locomotive works of the Great Western Railway Company at Swindon, as well as from the Trowbridge Coöperative Society Up to the present time £9607 have been subscribed towards the fund. Of this sum £3649 have been expended on the purchase of 50 acres of land levelling the site for building, and other preliminaries The maintenance of 12 beds is already provided for—four by the corporation of Bristol, two by Bath and Swindon respectively, and one each by Gloucester by Mr J Clark, by Mr and Mrs. W Clark, and by Messrs. Fry and Sons The first part of the building to be erected includes the administrative block for the institution and 20 beds. The cost of this will be about £6500 The completed scheme will be for 60 beds at an estimated cost of £20,000, while £4000 will be required for maintenance

A PROPOSED SANATORIUM FOR EMPLOYES OF THE GENERAL POST OFFICE.

At the conference of the Postal Telegraph Clerks' Association held in Leeds on March 7th a motion was adopted appointing a committee to investigate the means of providing sanatorium accommodation for postal employés. In the course of proposing the motion Mr C H Garland (London) said that the Post Office established staff in 1899 was 82,172 and there were 62 deaths and 83 retirements caused by consumption, a total loss of 145 persons. The total staff at present numbered over 179,000 and there was no reason to suppose that the rate of loss was less among the unestablished staff than among the established, so that it might be reckoned that from 300 to 350 persons per year fell victims to the disease The indoor staff was almost certainly the staff that suffered most, the loss being at least 2 per 1000 per annum Mr Garland then quoted at some length medical opinions as to the advantages of sanatorium treatment, making reference also to the "Report of the Association of British Postal Medical Officers on the Prevalence of Tubercle among the Employés of the Post Office during the year ending Dec. 31st, 1900" He then continued as follows —

> The cases of superannuation and death from consumption show that nearly two of every 1000 employés suffer seriously from this disease each year It is usual to reckon about ten times the number of deaths in order to arrive at the number of the sick, but I believe such an estimate would be much too high in the Post Office and it will be sufficient for our purpose to suppose that among the indoor staff about 4 per 1000 require treatment each year The last Postmaster General's report showed that the number in class H. or Counter Clerks and Telegraphists Sorters Sorting Clerks and Telegraphists and Telegraphists was 30 330 Among this body we can assume then that some 120 persons require treatment each year Each bed in a sanatorium would supply treatment for three or perhaps four patients each year Let us suppose only three, and to treat 120 persons we should require 40 beds. It is estimated that the cost of erection per bed is £200 so we can reckon that we want roughly £8000 for erection. The cost of maintenance would not exceed £65 per bed per annum. This would provide medical attendance nursing food, and medicine at no expense to the patient So that our financial requirements would be an initial outlay of £8000 and a yearly income of £2600 How are we to get this? If 30 000 persons consented to have 1*d* a week stopped from their salaries it would provide £125 weekly or £6505 per year So that if we could get the indoor staff to subscribe 1*d* per week for 64 weeks or about 15 months we should have our £8000 for erection and if they would then continue to subscribe a halfpenny per week it would yield about £3250 per year for maintenance.

In conclusion, Mr Garland said that he felt certain that no more than a very small percentage of the officials concerned would refuse to subscribe to such an object and that no serious difficulties would be encountered in collecting the subscriptions.

MEDICINE AND THE LAW

Private Bills affecting the Medical Profession.

AT this early period of the Parliamentary session there are already several Bills printed and awaiting the opportunity for their further introduction to the House of Commons which directly or indirectly affect the medical profession or some branch of it Some of these appear for the first time and some do not. Private members' Bills, it is well known do not form a large proportion of the legislative output of the year owing to various causes which need not be gone into, but it is well that their provisions should be known to those whom they concern Assistance may thus be obtained for useful proposals, the introducers of which can hardly be sorry to receive the support of expert opinion outside the House, and improvements or modifications may be suggested in matters of detail by those best qualified to express upon a basis adequate to supply efficiently all the needs of the residents within the county of London

The Hon. SYDNEY HOLLAND said that one difficulty in procuring the combination of hospitals was the objection raised by the medical staffs He failed to understand what Sir Henry Burdett intended as regards the Tottenham Hospital being helped by the London County Council. It appeared to him that the course proposed would municipalise the hospital. Turning to the suggestion that the Poor law infirmaries should be thrown open for medical instruction he expressed his opinion that these infirmaries were of no use for such a purpose He did not see any objection to the chronic cases going to Poor law infirmaries—the patients did not lose their right to vote in consequence of such a measure and they were not called paupers

Sir HENRY BURDETT, replying, said that a medical man in practice had to treat all sorts of cases and there was a vast amount of material for medical education which was wasted in the Poor law infirmary If medical students were admitted into the Poor law infirmaries it would be a great aid to their efficiency in actual practice afterwards.

Mr T B CAMPBELL said that in considering the question of moving hospitals they must recollect that they were dealing with voluntarily supported institutions He spoke from his own experience of the Westminster Ophthalmic Hospital.

Mr F S FRANKLIN said they had heard that it was the intention of King Edward's Hospital Fund to bring pressure to bear upon certain hospitals to induce them to move into other districts The mere ventilation of their views at that meeting would not do much

Mr C W THIES, of the Royal Free Hospital, said that the general hospitals from the very nature of their work were obliged to concentrate their attention on acute cases The chronic cases had to be drafted off. It had been stated that 23 per cent. of the cases that were termed "interesting" were sent up from the country Such cases were always welcome on account of their use in medical education and because in the country there was no satisfactory accommodation for their treatment.

Dr T GILBART SMITH said that the London County Council accepted as one of its duties the supply of bands of music for the amusement of the people In his opinion it was also the duty of the London County Council to supply hospital accommodation at Tottenham for the population it moved there With reference to the value of Poor law infirmaries for medical instruction he asked whether they would ever have learnt of Charcot's disease unless Professor Charcot had been a physician in an institution in Paris corresponding to a Poor law infirmary

Sir E HAY CURRIE said that the question of moving the hospitals must be approached in the most gentle manner possible He was of opinion that accommodation should be supplied for the incurable cases of consumption and the neglect of that precaution would be disastrous in the future

Sir TREVOR LAWRENCE said that he disagreed with Sir Henry Burdett concerning his figures of the populations in and about London Sir Henry Burdett had said that the people who came into London day by day might be taken as healthy, but it had been estimated that there was a daily influx to the meat and other markets surrounding St Bartholomew's Hospital of about 40,000 He was afraid that they were not all healthy Many of them had to do their work and earn their daily bread even if they were only able to move about. He further pointed out that if the census had been taken on a Monday morning instead of on Sunday night, when everyone was out of the City who could be the result would have been different In dealing with the question of moving the hospitals the desirability of economising the time of the physicians and surgeons who gave their services to the hospital should not be overlooked. Reference had been made to the patients being sent up to the London hospitals from the country districts. These patients were sent by medical men who had studied at the great metropolitan medical schools and they advised these patients to come from the country for the purpose of receiving the highest medical advice He could not conceive of any worse service to the poor and suffering than the placing of obstacles in the way of their receiving advice from leading physicians and surgeons. In regard to the London County Council and the Tottenham Hospital he thought that the proposed step would be the first advance of that ambitious body towards acquiring control over the hospitals He suggested that the London County Council should concern itself with relieving the hospitals from the rates and he would remind it that in consequence of the hospitals great relief was afforded to the ratepayers

A vote of thanks to Sir Henry Burdett for his address was moved by Mr TIMOTHY HOLMES, seconded by Mr P MICHELLI, of the "Dreadnought" Seamen's Hospital, and duly carried.

Sir HENRY BURDETT, in replying, denied that the proposals in regard to the London County Council and the Tottenham Hospital carried them a step further towards the municipalisation of hospitals

The meeting concluded with a vote of thanks to the Chairman, proposed by Sir HENRY BURDETT and seconded by Mr THOMAS BRYANT, which was carried with acclamation and suitably acknowledged

ROYAL EDINBURGH ASYLUM FOR THE INSANE

THE statutory annual meeting of the corporation of the Royal Edinburgh Asylum for the Insane was held in the City Chambers on Feb 23rd The annual report of the managers stated that the average number of all classes of patients under treatment during the year was 947, an increase of seven on the average number during the previous year In addition to this the asylum authorities had been obliged to find accommodation in other asylums for 123 patients sent to them by the Edinburgh parish council whom it was impossible to accommodate in the asylum itself These patients had been boarded out in the asylums of Hartwood, Larbert, Kirklands, and Rosewell. The constantly increasing number of pauper patients sent to the asylum by the parochial authorities was a source of much trouble and anxiety to the asylum officials Towards the end of last year the matter reached an acute stage, for the wards of the asylum became much overcrowded, while at the same time there was little or no prospect of further relief being obtained by boarding out This state of affairs was the result of the failure of the District Lunacy Board to complete the new asylum at Bangour within the stipulated period of five years. It was impossible to say at what time the Bangour Asylum would be ready for occupation, but the District Lunacy Board, on the solicitation of the managers of the Royal Edinburgh Asylum, supported by the General Board of Lunacy, had agreed to erect a temporary structure capable of accommodating 150 persons. This temporary accommodation would be ready in about four months' time and would to some extent relieve the existing congestion in the Edinburgh Royal Asylum. The large number of rate paid patients at present in the asylum excluded, as had been often pointed out, the poorer class of patients not dependent on parochial relief, for whom the West House was primarily intended. It was interesting to note that there had been 22 voluntary patients under treatment in the asylum during the year under the provisions of the Lunacy Act of 1862.

The ordinary revenue for the year had been £60,089 10*s* 5*d*. and the ordinary expenditure £55,075 3*s* The gross surplus revenue was thus £5014 7*s* 5*d* Deducting from this £1909 18*s* 8*d*, the annual instalment towards liquidation of the debt on the West House, there remained a free surplus of £3104 8*s* 9*d* Of that surplus £2300 9*s* 4*d* were derived from Craig House, £42 2*s* 7*d* from intermediate patients, and £761 16*s* 10*d* from pauper patients The cost of maintenance per head in Craig House was £131 1*s* 7*d*., nearly £6 more than in the previous year This rise was due partly to an increase in the number of patients paying high rates of board, and consequently demanding more expensive diet and more attention, and partly to the expenditure of £850 for the renewing of the cooking apparatus as well as £408 10*s* 8*d* for the purchase of accumulators in connexion with the electric battery The cost of maintenance per head of the intermediate patients had been £41 10*s* 7½*d* rather less than the amount for the previous year The cost of maintenance per head of pauper patients had fallen to £31 15*s* 8½*d*, as compared with £33 2*s* 4*d* in 1901. This decrease was due to a fall in the cost of provisions, fuel, furnishings, and repairs The managers proposed to reduce the rate of board for patients paying the lowest rate and for pauper patients to £32, or £30 exclusive of clothing

During the year the debt on Craig House and the West House had been reduced by £5010 14*s* 8*d* 34 patients had covered, and that an additional minimum fee of 1s per mile should be paid for each journey over two miles for each mile or part of a mile.

5, 6, and 7 These resolved that school children should all be compelled to produce a certificate of successful vaccination that there should be compulsory revaccination between the ages of 10 and 14 years and that "successful" vaccination should be defined in any future legislation.

8. That in the public interests all the institutions for the provision of calf vaccine in this country should be open to Government inspection and that no imported lymph should be used from any institution which is not recognised by the English Government

9. That there should be a Government vaccination station for the supply of lymph in all numerous centres of population.

10. That "efficient" vaccination should be defined as at present fixed by the Local Government Board as four insertions and half a square inch of cicatrix, and that the number of insertions and successful pustules be named in the certificate and registered by the vaccination officer.

11. That every medical practitioner not acting as public vaccinator who forwards a certificate to the vaccination officer of any efficient vaccination be paid a fee for the certificate provided that such certificate gives the number of insertions and successful pustules, and that such fee should not interfere with that charged for the operation

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

On Epidemic Small pox in the Union of Orsett 1901–02 by Dr G S BUCHANAN [1]—The Union of Orsett which has a population of some 33,000, is situated in South Essex and extends from west to east about 14 miles and from north to south about seven miles the Thames forming its southern boundary throughout The most populous portions of the union are the riverside neighbourhoods between Purfleet on the west and Tilbury on the east. The town of Grays lies midway between Purfleet and Tilbury and forms the Grays urban district, the rest of the union is comprised in the Orsett rural district. During the ten months from September 1901, to June, 1902, small pox appeared in 12 out of 17 parishes in Orsett rural district, the attacks per 1000 of the population in those parishes being 18 5, while in Grays urban district 16 per 1000 of the population suffered from the disease. The epidemic was thus of great severity It may be contrasted with the London borough of Holborn which suffered most heavily during the recent outbreak in the metropolis, where the attacks of small pox per 1000 during 11 months ending June 1902, were no more than 7 2. Dr Buchanan gives tables showing the incidence of small-pox week by week on the population and on dwellings in various subdivisions of the union. The epidemic had its beginning (from September to November, 1901) among the small community of Purfleet and in persons living elsewhere in the union where the attacks could be referred to infection from others who had contracted infection at Purfleet. From the middle of November, 1901 onwards the disease became prevalent over the whole of the southern portion of the union, its incidence being especially severe upon the villages of West Thurrock and South Stifford, which lie between Purfleet and Grays and upon the parish of Aveley which adjoins Purfleet on the north. The report deals in detail with the condition of the population of the union at the beginning of the epidemic in regard to vaccination Since 1891 neglect of infantile vaccination had increased and from 1895 to 1900 more than one third of the children whose births were registered had not been vaccinated With the exception of certain special communities (which entirely escaped small pox) comparatively few persons of ten years of age or upwards were already revaccinated when the epidemic began Having regard to the large number of unvaccinated children it was fortunate that no instances occurred of the spread of small pox in schools such as happened in Gloucester in 1896. Nevertheless, it is noteworthy that out of a total of 519 cases admitted to the local small pox hospital no fewer than 100 were unvaccinated children under the age of ten years and that 22 of these children died. During the same period only 11 vaccinated children under the age of ten years were admitted each suffering from discrete small pox, and no death occurred among them. An instructive table prepared from data obtained by Mr Rea Corbet shows with regard to adults that the fatality from small-pox in the unvaccinated was much greater than in the primarily vaccinated and this, not only at ages from 10 to 25 years (unvaccinated rate 14 3 per 100 primarily vaccinated rate 3 9), but also at ages over 25 years. 18 cases were admitted in which revaccination was stated to have been successfully performed at some period or other before infection by small-pox. In four cases this period was less than ten years, in one instance no more than six years. The progress of the epidemic caused a complete change in the attitude of the majority of the population towards vaccination. By March, 1902, as many as 6763 persons had been recently revaccinated and many children over one year had been recently vaccinated by the public vaccinators, while a large amount of revaccination and vaccination was performed by medical practitioners who were not public vaccinators. No case of small pox occurred among persons recently revaccinated save those who were already incubating small pox at the date of revaccination. The most striking facts of the epidemic, however were the severe and long continued prevalence of small pox in Purfleet and the evidence obtained which referred small pox in other parts of the union to infection contracted in Purfleet. In this village throughout the epidemic cases kept on occurring week after week and month after month, altogether 41 out of the 110 dwellings in the place were affected During the whole epidemic period in Purfleet and elsewhere there was no failure in the arrangements for isolation, cases of small pox being removed within 24 hours of notification, "contacts" were kept under observation, and disinfection, on the whole, was satisfactory There was little or no evidence that small pox in Purfleet was maintained by undetected cases or by supposed chicken pox. Moreover revaccination in Purfleet was freely resorted to On a liberal estimate those inhabitants who at the end of March, 1902, were not vaccinated children revaccinated or recently vaccinated adults, or persons who had suffered from small-pox did not exceed 40 Nevertheless, cases of small pox subsequently occurred among these 40, while other later cases in Purfleet were persons newly arrived in the place. These considerations, along with a number of others in the report which space does not allow us to summarise, are important in their bearing on the question of the convection of small pox infection from the Metropolitan Asylums Board's small pox hospital ships which are moored in the Thames off the Kent shore opposite Purfleet, from which they are separated by nearly half a mile of water There was no personal communication between the ships and Purfleet throughout the epidemic and in considering the influence of the ships, as Dr Buchanan puts it, 'we have to choose between aerial convection or nothing'

> As to the latter alternative I would say at once that if the presence of the small pox ships in Long Reach had no concern with the Purfleet epidemic, then, while making every allowance for opportunities of local spread of the disease I am nevertheless quite unable to suggest any reason for the extraordinarily heavy and long sustained prevalence of small pox there. If, on the other hand the ships did exert influence on the epidemic, infective particles being from time to time, under favouring meteorological conditions conveyed to the area of Purfleet and there reinforcing small pox already prevalent, or setting small-pox going anew then not only is the Purfleet experience intelligible but the hypothesis invoked to explain it is one that has been shown to be necessary in our present knowledge if the characteristic peculiarities in the distribution of small pox in the neighbourhood of small pox hospitals are to receive anything approaching a sufficient explanation.

Those who are interested in the question will note with interest the abundance of circumstantial evidence given in the report that the ships were responsible for disseminating infection in their neighbourhood in the way in which the London hospitals of the Metropolitan Asylums Board used to do when they received acute cases of small pox. Instances were traced, for example, in which members of the crew of vessels moored for a while in Long Reach sickened with small pox about 12 days afterwards. It is, of course, impossible to test the matter in this case by looking for graduated intensity of incidence of small pox in dwellings near the hospital ships, there are practically speaking no dwellings within a mile of the ships save those in Purfleet and the Dartford marshes to the south of the ships are uninhabited. But during the period under consideration large numbers of workmen were employed opposite the ships on the Kent shore in the erection of temporary buildings and among these men cases of small pox occurred almost by the score. Unlike the inhabitants of Purfleet these men may have had opportunities of mediate infection by association undetected by the authorities with members of the opinions. On the other hand, attention may be called to suggested measures which are likely to prove futile or obnoxious and their failure to become law may thus be rendered more certain.

Medical Acts Amendment Bill

The private members' Bill before the House of Commons which is of most importance in that it concerns the medical profession more or less as a whole is introduced by Sir John Batty Tuke, while it further bears the names of Sir John Gorst, Mr James Campbell, Sir Richard Jebb, Mr Talbot and Sir Michael Foster Its principal objects are to give the General Medical Council power to erase from the Medical Register for a limited period the name of a registered practitioner who has been guilty of a crime or who has been adjudged guilty of infamous conduct in a professional respect, and to enable the medical authorities—that is to say, the universities and other bodies entitled to grant medical diplomas—summarily to deprive a practitioner whose name has been erased from the Medical Register of the medical diploma obtained from that authority A third provision orders that, notwithstanding the provisions of any Act in force or hereafter to be passed, all fines and penalties recovered under the Medical Acts or the Dentists Act, 1878, shall go to the General Medical Council to be applied in aid of the expenses incurred by the Council in putting into force the Medical Acts. The changes proposed to be made require but little comment or commendation. At present the General Medical Council can inflict but one penalty, the erasure of the name of the person brought before it from the Medical Register The power to modify and to regulate the penalty to be imposed is a highly desirable one for any punitive body to possess, for many reasons One of these is that where the necessary penalty is not one of extreme severity offences are more likely to be complained of and punished than where the accusation, if successful, must necessarily involve the professional ruin of the accused The second proposed change enables the bodies which grant medical diplomas to withdraw them subject to their possible future restoration where the General Medical Council has exercised its powers of removal from the Register, this power to withdraw diplomas is not now possessed by all the bodies which may grant them. The third proposed change is due to the fact that in London the penalties referred to are claimed by the Receiver of Police under the Metropolitan Police Courts Act, 1839

A Public Health Bill

The full title proposed for this measure is "The Public Health (Officers' Tenure of Office and Superannuation) Act of 1903" It is introduced by Sir Francis Sharp Powell and is supported by Sir Walter Foster, Mr Talbot, Dr Farquharson, Mr Henry Hobhouse Mr Cripps, Mr Heywood Johnstone, Sir Michael Foster, and Sir John Batty Tuke. Its main objects are to insure that none but those properly qualified shall be employed as officers of health (a definition in which are included medical officers of health, sanitary inspectors, and inspectors of nuisances), to give to these as far as is reasonable security of tenure in their offices, and to enable them by definite contributions proportionate to their salaries, paid to a central fund, to provide for themselves superannuation allowances to assist them in the event of old age or disablement. The memorandum prefixed to the Bill calls attention to the highly technical duties performed by sanitary inspectors and points out that as the law stands urban and rural sanitary authorities may appoint officers of health on such conditions as to qualifications, tenure of office, and other matters as they deem fit. The body of the Bill would enact that no person should be appointed an officer of health unless he either is the holder of a certificate of the Local Government Board or of some body for the time being approved by that Board, gained by examination, or unless he has for three years before the passing of the Act served as an officer of health This portion of the Bill is, no doubt, to a large extent designed to obtain the appointment of competent sanitary inspectors, the qualifications of these for their posts being less easy to appreciate in existing circumstances than those of medical men who offer themselves for the posts of medical officers of health. It also proposes to do away with the term "inspector of nuisances," substituting for it the more euphonious one of "sanitary inspector" Conditions of superannuation are proposed, followed by a scale of superannuation allowances These range from fifteen sixtieths of the average annual salary of the last five years of service, payable after a service of ten years, to forty sixtieths, a maximum only to be obtained after 35 years service. The proposed deductions from salary as contributions towards these allowances are graded from 2 to 3 per cent according to the time of service. Contribution by those already holding office is to be according to choice and various matters of detail financial and otherwise, are considered in various sections devoted to them. Enough has been said to show that the measure is one of considerable importance to the two classes directly affected by it.

An Anti Vaccination Bill

A brief Bill, containing but one operative section, would order that "a vaccination officer shall not take proceedings against a parent or other person under section 29 or section 31 of the Vaccination Act, 1867, except with the express sanction and authority in each case of the guardians of the union or parish for which he acts." This attempt to repeal the Vaccination Acts locally at the option of a more or less uneducated majority of the enfranchised population embodies the present ambitions of the anti vaccinationist, as already shown in a succession of defences to prosecutions and subsequent appeals. It is, perhaps, not likely to receive the serious consideration of the House of Commons, and it is to be hoped that if it does its rejection will be decisive. It is introduced by Mr Channing and is supported by Sir John Rolleston, Mr Goddard Mr Cremer, Mr Brigg, Mr Broadhurst, Mr Corrie Grant, and Mr Bell

An Anti Vivisection Bill

This Bill seeks to amend 39 & 40 Vict. c. 77, the statute which already regulates and controls the performance of experiments upon live animals Its main object appears to be the abolition of the existing provisions for the performance of certain experiments under certificates, which without such certificates are not permissible. Those especially aimed at are no doubt those in which it may be desired to dispense with the administration of an anæsthetic. There is also in the Bill a section ordering that "there shall be present during and throughout the whole course of the experiment an inspector," "and no such experiment shall at any time be performed or continued save in the presence of such inspector as aforesaid." Power is given to the Secretary of State to appoint a sufficient number of inspectors for this purpose Their duties would, however, obviously be such as only highly qualified members of the medical profession could adequately perform and the questions to be decided by them are now safely left in the hands of the highly qualified members of the medical profession whose experiments at times under the existing Act lawfully include those upon live animals These experiments are already subject to conditions with regard to inspection and other matters, the stringency of which it is proposed, should be increased in other directions besides those to which we have called attention. Members of Parliament who have considered the existing Act and are acquainted with the statistics relating to its subject matter will for the most part be satisfied that the protection which it affords to dumb animals is sufficient without the additional restrictions proposed in a Bill which is brought in by Sir Frederick Banbury, Colonel Lockwood, and Mr MacNeill.

MEETING OF PUBLIC VACCINATORS AT PLYMOUTH

A MEETING was held in the room of the Plymouth Medical Society on Feb 28th to elect a district council from among the public vaccinators of South Devon and North and East Cornwall (including members and non members of the Association of Public Vaccinators of England and Wales) Mr G Jackson of Plymouth presided The following resolutions were adopted unanimously —

1 This resolution referred to the constituting of a district council.

2. That the Local Government Board should be the authority to which the administration of vaccination should be intrusted.

3. That failing the entire transference of administration from boards of guardians to the Local Government Board it is absolutely necessary in the public interests that the public vaccinator should be as independent in position as the vaccination officer

4 That the minimum fees cannot be fairly reduced and in many country districts they are inadequate on account of the distance to be

been three, three, and five in the three preceding weeks, declined again last week to three. The fatal cases of diarrhœa, which had been four, one, and four in the three preceding weeks, decreased again to two last week. The 202 deaths in Dublin last week included 34 of children under one year of age and 59 of persons aged 60 years and upwards, the deaths of infants showed a slight excess over the number in the preceding week, while those of elderly persons showed a considerable increase. Six inquest cases and six deaths from violence were registered, and 76, or more than a third, of the deaths occurred in public institutions The causes of 18, or nearly 9 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

Staff Surgeon Bassett Charles Edward Fitzgerald Gunn has been promoted to the rank of Fleet Surgeon in His Majesty's Fleet. Dated Feb 26th, 1903.

The following appointments are notified —Staff Surgeon E. A. Penfold to the *President*, additional for three months' course of hospital study Surgeons W R. Harrison to the *Boscawen* for the *Wanderer*, J G Peebles to the *Boscawen* for the *Dolphin*, W G Edwards to the *Boscawen* for the *Seaflower*, F E Bolton to the *St Vincent* for the *Martin*, S S. H. Shannon to the *Impregnable* for the *Nautilus*, R. L. Jones to the *Impregnable* for the *Pilot*, R. H. Atkins to the *Lion* for the *Liberty*, all lent for cruising season, E T P Eames to the *Torch*, and on recommissioning, and T W Miles to the *Jupiter*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel E H. Fenn, C E I, from the Seconded List, to be Lieutenant-Colonel. Dated Feb 19th, 1903

The undermentioned Lieutenants are confirmed in that rank —A. B Smallman, W F Tyndale, C M G, P Davidson D S O, W F Ellis (on probation), J McKenzie, W B. Taylor, H. D Walker, A. H. Hayes, H J Crossley, R. B Ainsworth, C A. J A. Balck R Storrs, R L V Foster, F A. H Clarke, G A. K H Reed, G W Smith, J W S Seccombe, J M H. Conway, S M W Meadows, H. V Bagshawe D S Skelton, C N B Stanley, H G S Webb, W W Browne, F L Henderson (on probation), R. Rutherford, W D C Kelly, N E. J Harding, W C Rivers, and R. J Franklin.

INDIAN MEDICAL SERVICE.

The King has approved of the following appointments — To be Colonel, Bengal Establishment Lieutenant-Colonel Henry Hamilton. Dated Oct. 1st 1902. This cancels the notification of this officer's promotion made in the *London Gazette* of Jan 16th, 1903. Bombay Establishment Lieutenant-Colonel Arthur Henry Cole Dane. Dated Oct 30th, 1902 To be Lieutenants (dated Sept. 1st, 1902) John Hanna Murray, Frederic Percival Mackie, Arthur Tregelles Pridham, John O'Leary, Samuel Rickard Christophers, Harry Emslie Smith Hugh Reginald Dutton, Vincent Blumhardt Nesfield, Henry Martyn Brown, Francis Peter Vieyra, Arthur Frederick Pilkington, Philip George Easton, Wilfrid Wynne Jeudwine, Thomas Charles McCombie Young, George Adam Jolly, Henry Coddington Brown, Abdurrahman Khan Lauddie, Walter Julius Collinson, Cuthbert Lindsay Dunn, Herbert Michael Henry Melhuish, Horace Harvard Kiddle, Richard Francis Chetwynd Talbot, Raghuber Dayal Saigol, Cecil Edward Bulteel, John Lumsden Lunham Frederick Collen Rogers, Maung Ba Ket George Frederick Humphreys, and Clayton Alexander Francis Hingston

The King has also approved of the retirement from the service of the undermentioned officers —Lieutenant Colonel Maneckjee Eduljee Reporter, Madras Establishment. Dated Nov 27th, 1902. Lieutenant-Colonel Alexander William Mackenzie, Bengal Establishment. Dated Jan 31st, 1903

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon Captain Henry Waite, 2nd West Riding of Yorkshire Royal Engineers (Volunteers), to be Surgeon Captain Dated March 11th, 1903.

VOLUNTEER CORPS.

Rifle 1st Volunteer Battalion the Royal Scots Fusiliers Supernumerary Surgeon Lieutenant J O Taylor, *from the* 9th Lanarkshire Volunteer Rifle Corps to be Surgeon Lieutenant. Dated March 7th, 1903. 4th (Nottinghamshire) Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment) Arthur John Helm Montague to be Surgeon-Lieutenant. Dated March 7th, 1903. 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry) George Symers Mill to be Surgeon Lieutenant. Dated March 7th, 1903 21st Middlesex (the Finsbury) Charles Allen Casterton Smelt to be Surgeon-Lieutenant. Dated Feb 24th, 1903. 1st (Hallamshire) Volunteer Battalion the York and Lancaster Regiment Captain D G Newton, from the South Yorkshire Volunteer Infantry Brigade Bearer Company, to be Surgeon Captain. Dated March 7th, 1903.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY

Welsh Evelyn John Robert Evatt to be Surgeon Lieutenant Dated March 7th, 1903

CHURCH LADS' BRIGADE MEDICAL CORPS.

We have received a new and enlarged edition of the manual for the Church Lads' Brigade Medical Corps published at the headquarters of the brigade, 13, Craven street, Charing Cross, London, W C The manual is based upon the manual of the Medical Staff Corps and contains a brief outline of the structure and functions of the human body and its organs and instruction for first-aid to the injured. Special attention has been given to drill which has been brought into line with the present army medical regulations and it is suggested that the manual will be found of value to cadet corps, schools, and similar organisations where military drill and ambulance teaching are utilised. The section dealing with poisoning is short and to the point, but we cannot entirely indorse the "Table of Special Poisons and their Treatment." The class for whom the manual is written will rarely, if ever, meet with cases of poisoning from several of the poisons there specified, while, on the other hand, all reference to food poisoning is omitted. Emetics are recommended in the table in cases of carbolic acid poisoning, without any reference being made to the anæsthetic or corrosive actions of that substance. On the other hand, on p 59 carbolic acid is classed with the corrosive poisons and emetics are forbidden

THE REFORM OF THE ARMY MEDICAL DEPARTMENT

In the course of his statement in the House of Commons on army reform on March 10th Mr Brodrick said that the present year had been a notable one in the reorganisation of the Army Medical Corps. He believed that the House of Commons owed a large measure of gratitude to those eminent civilian surgeons and medical men who had joined, on public grounds, the Advisory Board Sir Frederick Treves, Bart, K.C V O, C B, Mr A D Fripp, C V O, C B, Dr E C Perry, Dr J Galloway, Sir Charles B Ball, and others, had given immense time to the public service. While previously a sufficient number of candidates to fill vacancies could not be obtained at the first examination under the new system there were three times as many candidates as vacancies— the class of candidates being of a very high order A medical staff college had been established in London which would enable officers returning from foreign service to utilise to the best advantage that leave for study which they have never had hitherto and without which it was impossible to keep up their scientific attainments Specialisation in the Army Medical Service would be encouraged and everything would be done to bring the medical and surgical equipment of the army up to date.

DEATHS IN THE SERVICES.

Surgeon-Major Vere Edward Hunter, R.A.M C, at Bombay, on March 2nd He entered the Army Medical Department in 1883 and was promoted to the rank of surgeon major in 1895, He served for some years in Burma, where he joined the army on field service in 1887–88

THE TORQUAY WATER-SUPPLY —Referring to the leading article on Moorland Waters and Lead Poisoning, published in THE LANCET of Feb 28th p 596, Mr J Bentall Endean writes to us from Torquay on the subject of the water supply of that town. He says that the Torquay corporation supplies water to more than 45 000 consumers, that this water is derived from moorland gathering grounds including peat and bog that it is "peaty," and that all of it is delivered to the consumers without filtration. He is doubtful as to the wholesomeness of this water and calls attention to the prevalence of ulcer of the stomach, anæmia, and cancer, mentioning that out of a total of 504 deaths in Torquay in 1901 there were 44 due to cancer ships' staffs who had not changed their clothing or otherwise had failed to carry out the hospital rules as to disinfection. But the presumption that the bulk of the small pox among these workmen was attributable to aerial convection is very strong Dr Buchanan quotes also the instructive figures which Dr J C Thresh prepared for the Epidemiological Society on the incidence of small pox in the Orsett Union in previous years and which show that since the ships began to take acute cases of small pox in 1894 the place where small pox has again and again made its first appearance has been Purfleet or neighbouring portions of the parish of West Thurrock It will be remembered that Dr Thresh[2] when dealing with data obtained during the earlier periods of this epidemic gave reasons for inferring that infection conveyed aerially from the ships was responsible in considerable measure for the prevalence of small pox not only in Purfleet but also in parts of the Orsett Union distant from two to five miles in a direct line from the ships and that the incidence of the disease might be related to the direction of the prevalent winds. Dr Buchanan discusses this question in some detail and arrives at the conclusion that the evidence of the conveyance of infection to such distances is hardly sufficient in view of the impossibility of eliminating the factor of personal communication and traffic between Purfleet and other parts of the union. He points out that on theoretical grounds it is easier to realise the operation of aerial convection on still foggy days, when the large volume of warm air derived from the wards, accompanied by suspended particulate matter, rises steadily upwards from the ships and the particulate matter thus conveyed gets wafted by gentle air, currents without much dispersion, "ultimately to settle now, for example, on Purfleet, now on the Dartford marshes, at one time towards Erith, and at another on the surface of the river A moderate or strong wind, on the other hand, ought to be expected to cause rapid dispersion and removal of particulate matter rising from the ships." The report is illustrated by maps and contains appendices giving notes regarding the prevalence of small pox in the Dartford Union and meteorological data

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8693 births and 4790 deaths were registered during the week ending March 7th. The annual rate of mortality in these towns, which had been 17 1, 16 7, and 16 6 per 1000 in the three preceding weeks, was again 16 6 per 1000 last week. In London the death rate was 16 4 per 1000, while it averaged 16 6 per 1000 in the 75 other large towns. The lowest death rates in these towns were 6 3 in Handsworth, 6 7 in Newport (Mon), 8 1 in Wallasey, 8 8 in Barrow in Furness, 9 3 in Northampton, 9 8 in Smethwick, 10 0 in Hornsey, and 10 1 in Great Yarmouth and in Burton on Trent, the highest rates were 20 1 in Wigan and in Rotherham, 21 8 in Tynemouth, 22 1 in Newcastle-on Tyne 23 0, in Manchester, 24 2 in Preston, 25 7 in Swansea, and 27 5 in Coventry The 4790 deaths in these towns last week included 501 which were referred to the principal infectious diseases against 452 in each of the three preceding weeks, of these 501 deaths 142 resulted from measles, 142 from whooping cough, 77 from diphtheria 52 from scarlet fever, 42 from diarrhœa, 30 from "fever" (principally enteric), and 16 from small pox. No death from any of these diseases was registered last week in Brighton, Ipswich, Norwich, Burton on Trent, Walsall, Handsworth, King's Norton, Barrow in Furness, Rotherham, or Newport (Mon), among the other towns the highest death rates from the principal infectious diseases were recorded in West Ham, Hanley, West Bromwich, Wigan, Bolton, Salford Tynemouth, and Swansea The greatest proportional mortality from measles occurred in Nottingham, Wigan, Bolton, Manchester, and Swansea, from scarlet fever in Great Yarmouth, from diphtheria in West Ham, Bristol, Hanley Coventry, Salford Huddersfield, and Bradford, from whooping cough in Croydon, East Ham, Hanley, Oldham and Preston, and from diarrhœa in St. Helens. The mortality from "fever" showed no marked excess in any of the large towns Six fatal cases of small pox were registered in Liverpool, two in London, two in Birmingham and one each in Leicester, Bootle, Bury, Oldham, Leeds, and Cardiff, but not one in any other of the 76 large towns. The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had been six, eight, and five on the three preceding Saturdays, had risen again to six on Saturday, March 7th, two new cases were admitted during the week, against one, seven, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had declined from 2528 to 1851 at the end of the ten preceding weeks, had further decreased to 1791 at the end of last week, 194 new cases were admitted during the week, against 246, 205, and 197 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 267, 274, and 271 in the three preceding weeks, further declined last week to 251, and were 316 below the corrected average number Influenza was stated to be the primary cause of 31 deaths in London last week, against 24, 25, and 15 in the three preceding weeks The causes of 49, or 1 0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Leicester, Salford, Leeds, and in 45 other smaller towns, the largest proportions of uncertified deaths were registered in Reading Liverpool, St Helens, Blackburn, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had declined from 21 7 to 17 7 per 1000 in the four preceding weeks, rose again to 18 5 per 1000 during the week ending March 7th, and was 1 0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in these eight Scotch towns ranged from 13 2 in Paisley and 16 8 in Glasgow to 21 4 in Dundee and 22 1 in Edinburgh The 606 deaths in these towns included 32 from whooping cough, 21 from diarrhœa, 15 from measles, four from scarlet fever, two from "fever," and one from diphtheria, but not one from small pox. In all, 75 deaths resulted from these principal infectious diseases last week, against 85, 76, and 59 in the three preceding weeks These 75 deaths were equal to an annual rate of 2 3 per 1000, which was 0 6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 32, 26, and 23 in the three preceding weeks, rose again last week to 32, of which 18 occurred in Glasgow, five in Dundee, four in Edinburgh, and four in Leith. The deaths from diarrhœa, which had been 18 and 13 in the two preceding weeks, increased again to 21 last week, and included 10 in Glasgow, four in Edinburgh, four in Paisley and two in Aberdeen The fatal cases of measles, which had declined from 20 to nine in the preceding weeks, rose again last week to 15, of which seven were registered in Aberdeen, three in Glasgow, three in Edinburgh, and two in Leith. The deaths from scarlet fever, which had been eight, seven, and five in the three preceding weeks further declined to four last week and included two in Glasgow and two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns which had declined from 183 to 92 in the six preceding weeks, rose again last week to 97, but were 133 below the number in the corresponding period of last year. The causes, of 35 or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 25 0, 20 6, and 25 9 per 1000 in the three preceding weeks, further rose to 27 8 per 1000 during the week ending March 7th During the past four weeks the death rate has averaged 24 8 per 1000, the rates during the same period being 16 8 both in London and in Edinburgh. The 202 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 14 over the number in the preceding week and included nine which were referred to the principal infectious diseases, against 14, 18, and 14 in the three preceding weeks, of these, three resulted from whooping cough, two from diarrhœa, and one each from measles, scarlet fever, diphtheria, and "fever" These nine deaths were equal to an annual rate of 1 2 per 1000, the death rates last week from the same diseases being 2 0 in London and 2 1 in Edinburgh The deaths from whooping cough, which had saving of larger fees in important cases has not been brought to public notice I have an idea that there may be legal difficulty in paying proper fees to expert pathologists, but the same may be said of paying any fees at all to them

---

[2] THE LANCET, Feb 22nd 1902, p 496 and April 26th 1902, p 1172.

3. This brings me to my third point, which is that the position of Dr Freyberger is anomalous He has been appointed by the London County Council to perform post-mortem examinations in special cases The interpretation of the word "special" is left to Mr Troutbeck, but there can be no doubt that all inquests must resolve themselves into those where advanced and special pathological knowledge is required and those where the usual pathological equipment will suffice. In the latter cases the general practitioner is perfectly able to make the post-mortem examinations and to give the necessary evidence and Dr Freyberger's assistance at two guineas per case is an unnecessary extravagance In the far fewer cases where great special knowledge is required, Dr Freyberger may be able to fill the part, but the London County Council should not have appointed for the fulfilment of such important functions, the first gentleman who offered his services cheaply The post should have been advertised and application publicly invited In this way the public and the medical profession would feel that an attempt had been made to obtain the best man for an arduous appointment. The anomalousness of Dr Freyberger's position is that in most cases he is not wanted and that in the few cases where the expert pathologist is wanted the public has not a sufficient guarantee of his skill The Control Committee of the London County Council have recommended that the services of other experienced pathologists should be obtained and hope for the coöperation of the Royal Colleges of Physicians of London and Surgeons of England and of the big London hospitals in obtaining competent men. This is a real step forward. The recommendation has been adopted by the London County Council. It now remains to be seen, firstly, if any expert pathologists will be tempted by the small fee to offer their services and, secondly, if the coroners will be content to use their help only in *special* cases I am, Sirs, yours faithfully

LUNACY AND THE LAW—"SINGLE CARE"

To the Editors of THE LANCET

SIRS,—The able articles which have recently appeared in the medical journals from the pens of Dr E. W White and Dr T Outterson Wood and the letter of Dr H. Rayner in THE LANCET of March 7th, p 681 are well worthy of perusal by, and the serious consideration of, every member of the medical profession, be he alienist or consultant physician or engaged in the ordinary every-day practice of his profession, for they have raised a timely and a warning note, which is not to be disregarded, on this very important subject It is, perhaps, not too much to say that many of the communications which have appeared in the press lay and medical, on the law as it affects single care in the certificated, the uncertificated, or the so-called border line cases betray ignorance of the most elementary necessities and precautions which must be used in dealing with persons of unsound mind in whatever stage of the disorder, and that some of the suggestions set forth in all seriousness tend directly to the revival, or rather the establishment, speedily of all the evils which it has been the province of the various lunacy Acts, *ab initio*, to render impossible.

Amid much that is irrelevant and impracticable in the discussion hitherto there stands forward prominently and with unanimity one opinion and that is that only fully-trained, qualified, and experienced persons are fitted for the exceedingly delicate and tactful task of properly tending and ministering to the unsound in mind, whether the manifestations of the unsoundness be of the mildest or of the most exaggerated type To secure and to retain this trained intelligence for the care of the mentally unsound and to insure its exercise under the most favourable conditions for the patient is the problem of the hour which awaits solution It is acknowledged on all hands that many of those who now assume responsibility for cases under single care are not persons who come up to the standard indicated here. Surely a disordered brain and nervous system are in at least as much need of the specially trained physician and nurse as is a broken limb in need of the surgeon and his specially trained surgical nurse or some severe internal malady of the physician with similar aid to suit his requirements.

How are the desirable conditions herein set forth to be best attained and with as little disturbance as possible to the existing state of the law? At the present moment cases of mental unsoundness in any of their stages or varieties can be treated in hospitals for the insane or in private houses adapted for the purpose and licensed by the Commissioners in Lunacy or by magistrates, either during voluntary residence in one or other of them or under order and medical certificates, whilst the poor or pauper class are cared for in the various county or borough asylums. It may be taken for granted that in any of these institutions trained medical and nursing skill will be amply provided Why not, then, go a step further in the same direction and authorise by law that "single care" be constituted on similar lines under licence by Commissioners in Lunacy or magistrates who in granting such licences would hold themselves responsible for the suitability of the provision made for single care in every respect, as well as for skilled medical and nursing treatment? Such a provision would at least insure that none but properly qualified persons and suitable premises and exercising grounds were provided, for licences would be granted to none other Single patients or boarders would thus also with certainty be brought under the very necessary supervision of commissioners and magistrates, evasions of the law would be more easily detected, and serious abuses of any kind would certainly be abolished or minimised. Physicians who have hitherto felt themselves debarred from the single care of their patients by fear of being brought under the operation of law while so doing would thus be placed at rest and feel in tranquil security on this point whilst engaged in their duty

I am, Sirs, yours faithfully

West Malling March 7th 1903 JAMES ADAM.

THE LIMITATIONS OF THE GENERAL MEDICAL COUNCIL

To the Editors of THE LANCET

SIRS,—As in your leading article under the above heading in THE LANCET of March 7th, p 671, you were good enough to refer to myself, I shall be glad if you will allow me to write a few words in reference to the question as to school board certificates which I submitted to the Executive Committee of the General Council of Medical Education and Registration You express some surprise that medical men, including myself, should have brought before the Council inquiries concerning the etiquette and conduct of the medical profession. Now, Sirs, I do not question for a moment the accuracy of your definition of the powers and duties of this body, but if the supreme authority on all matters pertaining to medical education and registration has no power to make regulations or to give advice concerning medical etiquette and what does or does not constitute improper or "infamous" conduct, I should like to inquire from what quarter a perplexed medical man can hope to obtain guidance in regard to the various thorny problems which members of the profession are liable to encounter To take, for instance, the various questions referred to in your article. All these, I think it will be admitted are matters concerning which it is desirable there should be some authoritative standard of conduct by which medical men may shape their course and it is, I think, evident from your comments that in regard to none of them is there any accepted regulation at the present time If, therefore, the General Medical Council has no power to decide on such matters, is it not much to be desired that its sphere of work should be extended in this direction or that some other body should be vested with the required authority? I do not wish now to go into the particular question as to school board certificates which I submitted to the Council, but I may remark that I was induced to put it by the discovery that there is a wide divergence of practice and opinion among metropolitan medical men on the subject —surely a very unsatisfactory state of affairs.

I am, Sirs, yours faithfully,

DENNIS VINRACE.

Alexander-square South Kensington S W March 9th 1903.

⁂ We did not intend to indicate exactly surprise that Mr Dennis Vinrace should have sought the views of the General Medical Council in the particular circumstances. We meant rather to express the opinion that medical men as a body do not appreciate what the General Medical

Correspondence.

"Audi alteram partem."

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST

To the Editors of THE LANCET

SIRS,—The crux of the matter is What are the circumstances requiring a specialist and who is to decide when he is to be employed? I must confess that I thoroughly distrust the seeming concession of the London County Council Their original idea was that there were too many inquests and that the sum paid was excessive, and that by removing what they considered the principal motive for which medical men refused certificates—namely, the fee—they would effect an economy of some £20 000, and it was to carry out this policy that Mr Troutbeck was appointed The fee to be paid to Dr Freyberger was to be two guineas and we are asked to believe that the local man will be called to give evidence as to facts and so swell the cost to three guineas for the medical evidence I do not believe it for a moment, the whole thing is a red herring drawn across the trail, and in support of what I say I inclose a statement of the post-mortem examinations held in the Battersea mortuary since Nov 22nd, which speaks for itself You will observe that more post-mortem examinations have been given to Dr Freyberger since the deputation to the London County Council than before

Mr Troutbeck has stated publicly that "general practitioners are not fit to make post-mortems and that no barrister would profess to know all the branches of his profession." Now I am not concerned as to the legal qualifications of barristers, though I am inclined to agree with Mr Troutbeck about their limitations, but I repudiate Mr Troutbeck as an authority on medical qualifications and as long as he holds the view that a general practitioner is not fit to make a post-mortem examination and acts up to it there can be no *modus vivendi* I take it that the London County Council instructions were communicated to all the metropolitan coroners, but not one of the others is acting as Mr Troutbeck does and even he confines his operations to Battersea and leaves Westminster alone In the circumstances I think we had better reserve judgment for some little time

I am, Sirs, yours faithfully,
LEONARD S MCMANUS, M D R U I.

St. John's hill March 10th 1903

[INCLOSURE.]

Date.	Total number of post mortem examinations	Number performed by Dr Freyberger
Nov 22nd 1902 to March 5th 1903	58	35
Jan. 1st to March 5th 1903	36	20
Feb 16th to Feb 28th, 1903	5	5
March 1st to March 5th 1903	5	4

To the Editors of THE LANCET

SIRS,—It is earnestly to be hoped, in the best interests of the medical profession that the discussion concerning the introduction of the special pathologist as a regular feature at coroners inquests will not be allowed to drop, although the London County Council have shown a conciliatory disposition Questions of vital interest are involved in Mr Troutbeck's procedure and they must not be lost sight of because the unfortunate tendency to personality makes discussion difficult or because the London County Council do not desire further trouble in the matter There are three things that must strike all those who have followed the controversy as being the particular ones that call for consideration. The first is the legality of Mr Troutbeck's attitude, the second is the economy under which may be included the efficiency, of employing the so called expert pathologist in any save very special cases, and the third is the anomalous nature of Dr Freyberger's position.

1. Mr Troutbeck has accepted an appointment at the hands of the London County Council, agreeing with them to employ Dr Freyberger to perform post-mortem examinations in special cases It appears to many well informed persons (apparently, Sirs, to yourselves) that by the Coroners Act Mr Troutbeck has not the discretion to instruct and to pay Dr Freyberger to perform post-mortem examinations for the purposes of inquests held upon persons whom he has not attended in a district where he does not reside. The Act may be wrong, but, if it is, Mr Troutbeck has no power to amend it He can, and does, plead that he is carrying out the wishes of the authority to which he owes his appointment, but he must not obey that authority, however absolutely he may agree with its views, to the point of breaking the law The legality of Mr Troutbeck's procedure should be raised immediately in the usual way—by calling the attention of the public auditor to Dr Freyberger's fees and asking to have them surcharged Any ratepayer in the district can do this and this is the first thing to be done. The London County Council acknowledge their inability to appoint an expert pathologist with a salary, but it is not at all clear that Dr Freyberger's services are requisitioned in a legal manner

2. Economy has been put forward by Mr Troutbeck as an argument for the employment of Dr Freyberger to perform post-mortem examinations in special cases. As was recently pointed out in THE LANCET, it is difficult to see where the economy of the innovation comes in. Dr Freyberger has offered to perform post mortem examinations for the London County Council at coroners' inquests in return for the statutory fee of two guineas But for two guineas the coroner can have the evidence of the medical man who had been in attendance upon the deceased *as well as* a report of the post mortem examination It will therefore be seen that the coroner cannot have medical evidence bearing upon the condition and circumstances of the deceased while alive, *as well as* a report upon the post mortem appearances, unless he pays three guineas. An economical procedure which involves the spending of three guineas instead of two guineas could hardly escape criticism, and Mr. Troutbeck has seemed to design to dispense entirely with the evidence of the medical practitioner, so that although he saves no public money by the employment of Dr Freyberger he may at least lose none. I venture to think that his method of securing economy is as perilous as it is ineffective, it saves no money and lays the community open to grave risks which I mention, though to do so is to repeat what I have often read in THE LANCET The medical man who sees the circumstances in which the deceased was placed before death, the domestic environment, the behaviour of the relations, the state of the death chamber, and, perhaps, the position of the corpse before removal to the mortuary, must have opportunities of judging concerning the cause of death which will be quite denied to the specialist who is merely paid to make a post-mortem examination It must not be taken for granted that, because the employment of Dr Freyberger appears illegal, uneconomical, and futile in many cases, there is never any room for an expert pathologist at a coroner's inquest. While every qualified medical man possesses the ability to make a post-mortem examination in an every day case, it can easily be seen that circumstances will arise when the range of ordinary professional knowledge does not suffice for the giving of evidence which may be fraught with consequences of the gravest importance to other parties. In such cases it is quite right that the coroner should be assisted by having the necropsy conducted by some scientific man of known pathological and forensic attainments. Such expert witnesses are not numerous and it should be no more possible to offer them a fee of two guineas for their services than it would be to offer, say, Sir Edward Clarke the same sum as a fee with brief The real economy of the innovation which it is being attempted to introduce into coroners' practice by Mr Troutbeck, in agreement with the London County Council, is the dispensing with the services of the highly paid expert. By the payment to Dr Freyberger of two guineas for his services at so called special cases (the special circumstances of some of the cases where Dr Freyberger has been employed are not very obvious) the payment of proper fees to expert pathologists in cases of serious difficulty is eluded. It is not certain that the community would consider that such economy was worth having if they understood its meaning, and it is noticeable that, whereas the necessity of saving the guineas to be paid for the medical evidence of the general practitioner has been insisted upon by Mr Troutbeck, the

with a form of application for membership to each police surgeon whose name I have been able to find in the Constabulary Almanack As, however, this does not contain a complete list, and as I am anxious to secure the membership of every police surgeon willing to join, I will send a copy to any who will forward to me his name and address.

I am, Sirs, yours faithfully,
FRED W LOWNDES Honorary Secretary
40, Knight-street Liverpool, March 5th 1903.

THE CULTIVATION OF ANAEROBIC BACTERIA

To the Editors of THE LANCET.

SIRS,—Will you permit me to thank Dr. Klein for drawing my attention to his method of anaerobic plate culture as set forth in the medical officer's report for 1897–98. I am quite familiar with this method, as also with those of Gabritschewsky, Botkin, Hammerl, and other investigators who have worked at this subject. But in my hands these methods have not given uniformly satisfactory results, as, for instance, in the plate culture of such a strictly anaerobic micro-organism as bacillus tetani.

Dr. Klein's method and mine are the same in principle but in apparatus they differ I use a chamber having a very small air space provided with most efficient seal, whereby the vacuum created by the absorption of oxygen by the pyrogallic solution is maintained. In apparatus of the bell glass pattern having a large air space I have found that this is not always the case.

I am, Sirs, yours faithfully,
H S. FREMLIN.
Government Lymph Laboratories, Chelsea Bridge, S W

A DISCLAIMER.

To the Editors of THE LANCET

SIRS,—The report of an interview which appeared in the *Daily Telegraph* of March 3rd was published entirely without my authority or knowledge. I was quite unaware that the gentleman who engaged me in casual conversation in the office of the secretary of the hospital was a reporter

I am, Sirs, yours faithfully,
Cavendish-square W March 9th 1903. DUNDAS GRANT

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Indiscriminate Sale of Cocaine in India —Paralytic Affections among Men and Cattle in the Central Provinces —The Cremation Society of Bengal.—The Plague Epidemic —Reorganisation of the Health Department in Bombay

THE Bombay High Court in a test case instituted at the instance of the Government of Bombay has held that cocaine is not an intoxicating drug within the meaning of the Excise Act. The effect of this ruling will apparently be that no licence such as has been insisted on by the Governments of Bengal and Bombay will be necessary for the sale of cocaine and that the law as it now stands is powerless to check the cocaine habit which, as I have previously reported, is spreading rapidly in many parts of India.

In consequence of the spread of a paralytic affection attacking human beings as well as cattle in parts of the Central Provinces an official inquiry is to be held The complaint is due, it is believed to the eating of certain classes of dhal, more particularly that known as kasari dhal, or latri. As the botanical name for this is lathyrus sativus the complaint will probably turn out to be a long recognised one. The natives recognise its poisonous properties in both themselves and their animals but partake of it on account of its cheapness. Horses and bullocks lose control over the hind limbs becoming paralysed. This grain is also said to produce dyspnœa and roaring in horses when put to work Many years ago a widespread occurrence of paralysis in Sindh, after a season of extensive inundations in which kasari was grown on an exceptionally large scale, drew attention to it, and in the Azamgarh district, where paralysis is common, kasari forms an important article of diet.

The Cremation Society of Bengal, which now numbers nearly 100 members, is being registered under the Companies Act and hopes to obtain the control and management of the crematorium which the corporation proposes to erect.

The plague mortality continues to increase Last week 25 870 deaths were reported throughout India, against 24 500 in the previous seven days and 15,165 in the corresponding week of last year The Bombay Presidency returns 11,922 deaths, the Bengal Presidency 2817, and the Madras Presidency 592 Then we have the Punjab with 3735 deaths, the Central Provinces 206 the United Provinces 2599 the Mysore State 694, the Hyderabad State 932, and Berar 462 Bombay city reported 612 deaths from plague alone, Calcutta 142 Poona 849 and Karachi 33 When it is borne in mind that Poona contains only a little over 100,000 inhabitants the frightful mortality going on there will be recognised. Dr Shave, one of the plague medical officers now at Sholapur, has been selected for appointment to the Indian Medical Service

The health department of the Bombay municipality has been rearranged. Bombay is now divided into three divisions, each under the charge of a health officer For purposes of registration the city has been divided into ten registration districts, in each of which there is a municipal dispensary At each office there are a qualified native medical man and three hospital assistants who inquire into the cause of every death, investigate cases of infectious disease, and take action for removal to hospital. They also treat cases of sickness at the homes of the people in poor and urgent cases A nurse who is a qualified midwife is attached to each district. Dr J A. Turner is the executive health officer and Dr C H. Cayley, Mr W Venis, and Dr Sorab C Hormusji are the divisional health officers.

Feb 12th

THE
ORGANISATION OF THE PROFESSION

(FROM OUR SPECIAL COMMISSIONER.)

The Situation at Cardiff —The South Wales Colliery Surgeons and the Poundage System, the Satisfactory Payments obtained —The Question of Concentration or of Subdivision in Medical Practice

THOUGH, as recently described, a notable effort has been successfully made to organise the profession at Swansea it must be admitted that, taking South Wales as a whole, but little has been done. The only other organisation brought to my notice was the East Glamorgan and Monmouthshire Colliery Surgeons' Medico-Ethical Society At Cardiff, for instance, which is the most important town in South Wales, there is no medical union and this notwithstanding the presence of Mr T Garrett Horder who has made praiseworthy efforts in regard to the question of hospital abuse Nevertheless, there seems to be a total absence of public spirit among the members of the profession at Cardiff Some of the practitioners appear to fear having to subscribe to yet another institution and they complain that there are already so many calls made upon them. Nor is there any indication that they have realised that under its new constitution the British Medical Association, which is to meet so near to them this year, should be able to take economic questions in hand. It is doubtful if anyone has prepared any sort of statement or proposal or has fully grasped the leading potentialities of the new conditions and methods of organisation. On the other hand, there is this excuse—namely that the rate of payment for contract work at Cardiff is higher than it was at Swansea. The members of clubs for the most part pay 1*d* per week and these are not family clubs It will be remembered that at Swansea the average pay was 1½*d* per week, or 6*s*. 6*d*. per annum for family clubs. Such family clubs as exist at Cardiff pay I am told from 10*s* to 13*s* per year per family Nevertheless, the dockers medical aid organisation only pays 8*s* 8*d* per family, however, this latter and smaller figure is not lower than the terms accepted at Swansea. But, as one of the local practitioners explained, it is not so much the amount the members pay as the habits that prevail among them. In some societies or clubs the members may be impressed with the very just idea that as they pay so little they should only seek the advice of their medical officer when there is really need of

Council can and cannot do The General Medical Council is frequently blamed for supineness in situations where it has no possible power or discretion to act. Of course, the Medical Acts require amendment in the interests of the public and amendment in some directions might take shapes that would render the Council more practically useful to the medical profession.—ED L

COLLECTIVE INVESTIGATION OF PUERPERAL ECLAMPSIA

To the Editors of THE LANCET

SIRS,—The request of the Clinical Society of Manchester for reports of cases of eclampsia is meeting with a hearty response from medical men all over the country The committee would like to point out that a diminution in the excretion of urea is coming to be regarded as an important physical sign of the pre-eclamptic state, more important, perhaps than albuminuria The vital point is one on which they hope their investigations will throw much light and reports which give quantitative estimations of urea and daily quantity of urine will be doubly valuable for this reason

The use of the hypobromite process with Southall's ureometer is very simple and the apparatus is inexpensive (it can be obtained through any druggist for about 3s) It may perhaps be hoped that those who are favouring us with reports of cases will find time to furnish data enabling us to correlate the output of urea with the gravity of the case

We are, Sirs, yours faithfully,
T ARTHUR HELME,
President.
J PRICE WILLIAMS
Honorary Secretary for the Investigation
J HOWSON RAY,

22 St John street Manchester March 4th 1903.

THE LARGE INTESTINE AS AN INTERMITTENT SYPHON

To the Editors of THE LANCET

SIRS,—Quite apart from any opinion as to the theoretical merits of Dr R. W Leftwich's ingenious views as expressed in THE LANCET of Feb 7th (p 374) and 21st (p 552), clinical observation supplies us with a demonstration of the fact that the colon is capable, when its lumen is patent, of transmitting fluid by gravitation—using that term in the usual sense—more rapidly than by longitudinal and annular peristalsis. My first observation five years ago and many subsequent ones were made in patients suffering from typhoid fever and led to my adopting a method of treatment which I described under the heading of "postural treatment" in a note on "Suggestions for the Practical Treatment of Typhoid Fever" published in THE LANCET [1] I found that when the right loin was heavy and "dull" with fluid fæces, and the left loin resonant with gas, the cæcum and the sigmoid flexure could be made to exchange their contents and the character of their percussion note within a very few minutes by suitably tilting the bed or more simply the patient's body Moreover, the same exchange could be subsequently reversed by reversing the lateral decubitus—a point of some importance in treatment, as it enables the cæcum to be charged with irrigation fluid after it has been cleared of fæces. In cases of that kind my present practice, which I may describe as the "empty bowel treatment," is to empty the cæcum by posture into the sigmoid flexure where the fæcal fluid is within reach of the long tube or of an evacuating enema and then to irrigate the colon by means of a double tube with water containing charcoal powder in suspension. I now regard this daily toilet of the colon as belonging to the sanitary treatment of most cases of typhoid fever The other details of the treatment concern the upper bowel and do not bear upon the point now under discussion

I still consider that the rapid transmission of fluid through the length of the colon is mainly due to the alteration in the respective levels of the fluid and of the gaseous contents of an abnormally patent and atonic bowel, though I am prepared to admit that syphonage may come into play if at any moment the transverse colon and its flexures should become charged with an exclusively fluid column. The mechanism by which this syphonage might be brought about by posture and by other favouring circumstances might perhaps be illustrated by a simple schema consisting of a glass tube shaped like the colon (interrupted in the middle by a short length of indiarubber tubing) with one end tightly fitted into the neck of a flask containing water and the other end fitted into a flask containing air But no schema can teach us the complex working of the living bowel. It is possible that the gas contained in the cæcum may act under the influence of lateral pressure like the compressed air in the ordinary indiarubber hand ball pump in propelling the contents of the colon and sometimes in charging the transverse colon with a continuous column of fluid capable of syphonage However this may be, it is probable that our knowledge of the mechanical functions of the colon is far from complete, and Dr Leftwich's suggestive investigation has helped us to realise more clearly the many sided resources of the living bowel which may combine some of the properties of rigid tubes with the advantage of contractility I am, Sirs, yours faithfully,

Curzon street, W , March 8th 1903. WILLIAM EWART

THE VENTILATION OF SCHOOL BUILDINGS

To the Editors of THE LANCET

SIRS,—I should be very much obliged if you would allow me through the medium of THE LANCET to ask for an opinion upon the medical aspects of the following point in connexion with ventilation Certain systems of warming and ventilation are so arranged that the heating of the rooms is entirely done by the admission of hot air—that is to say, fresh air is propelled into the rooms but at a sufficient temperature to obviate the need of any further direct heating This plan is becoming more common and it would be very useful to have some opinions upon the hygienic aspects of breathing air which, to allow for the cooling effects of the windows and walls, must be when admitted very considerably above the required temperature of the room. Would not such conditions tend to have an enervating and depressing effect upon the vitality of the children, to weaken their powers of resistance to colds, &c ? It has been suggested to me that one result of this would be a tendency to adenoid growths, the system is very largely used in America, so that it would be interesting to know whether the complaint is more prevalent in that country than here where the plan, although in use in many places, has not been adopted to anything like the same extent I am, Sirs, yours faithfully,

FELIX CLAY

Buckingham street Strand W C March 4th 1903.

ADENOMA OF THE RECTUM

To the Editors of THE LANCET

SIRS,—In your leading article on this subject [1] you make the suggestion that an adenoma of the rectum may be a papilloma. I have examined a fair number of these growths and I have found that the greater number of them have no papillæ but are composed of tubes lying in a connective tissue stroma. If they have no papillæ how can they be papillomata? The commonest simple tumour of the rectum is the adenoma. The villous tumour, which is not so common, contains both papillæ and tubes and is an adeno-papilloma. I have never met with a pure papilloma of the rectum, although it is not improbable that they occur I have entered into the question of the nomenclature of these epithelial tumours in the Erasmus Wilson Lectures for 1902 [2] and in a communication to the *Journal of Pathology and Bacteriology* [3] a reprint of which I inclose.

I am, Sirs, yours faithfully,
CHARLES POWELL WHITE.
St Thomas's Hospital March 3rd 1903.

UNITED KINGDOM POLICE SURGEONS ASSOCIATION

To the Editors of THE LANCET

SIRS,—Will you kindly allow me to inform all those of your readers who are police surgeons of the following statement? I have forwarded a copy of our last annual report individual practice. This opens out an interesting scientific, practical, and economical problem. Is it better to have two leading men employing on the wages system six assistants and concentrating the responsibility and the work in their own hands, or else to have eight independent practitioners, each with his own individual practice and his small income to carry it out! Thus among the colliers and in regard to the methods obtaining for their treatment in sickness has the economic struggle between the rival principles of collectivism and individualism manifested itself. This is one of the several ways in which the economical evolution affects medical practice as it affects all the other economic conditions of modern civilisation.

MANCHESTER

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary

ALDERMAN SIR JAMES HOY, the late Lord Mayor, has prepared a report on the question of the Royal Infirmary site and its proposed purchase by the Manchester City Council. It has been approved by the subcommittee and will be presented for approval to the special committee appointed some time ago by the council to consider the question. It may be remembered that the late infirmary board fixed the price at £400,000 and the present board is not likely to accept less for it considers that it is worth far more than the £20 a yard at which it is offered. It could be, indeed, very well do so as it is stated that it has had a definite offer by a syndicate of £700,000 which puts the lowering of the price below the £400 000 out of the question. This sum indeed, is much less than what it would accept from any purchaser but the city itself. If the city council fails to secure this Piccadilly site, the finest in Manchester, for a great civic purpose it will illustrate once more the timidity and short-sightedness which lost it Trafford Park. That lesson, however was a severe one which it may be assumed is not yet quite forgotten. The report has not been made public but is said to contain suggestions forming an admirable basis of agreement It is desirable that, while there is no ill judged haste, there shall be no waste of time, for the pressure on the infirmary is very great. Indeed, Mr. John Thomson, the chairman of the board, said publicly on March 5th that 'he had only that day consulted with the doctors as to the practicability of erecting a temporary corrugated iron annexe." He hoped that the Corporation would buy the site and so enable a large and better infirmary to be built elsewhere

Manchester and Salford Sanitary Association

The annual meeting of the Manchester and Salford Sanitary Association was held in the town hall on Feb 27th After the adoption of the report, which gave an account of the previous year's work, a motion was passed approving of the efforts of the association ' to spread among the people a knowledge of the laws of health, to promote cleanliness temperance and thrift, to obtain a purer atmosphere, to improve the dwellings of the poor, and to preserve the lives of their children,' and declaring that these efforts "deserved a more adequate support from the general public" Major General Sir F Maurice addressed the meeting on the subject of the national health

The Salford School Board and the Physical Training of Children.

The Salford School Board has for some time devoted much attention to the physical welfare and training of the children in its schools and more especially since the appointment of a medical officer to the board in 1898 Careful inquiries are made as to the eyesight and hearing of the children and the medical officer makes a personal examination of those below the normal standard. Where glasses are advisable the parents are recommended to seek medical advice, and so also in many cases of defective hearing medical advice is suggested The head teachers of the older scholars have been directed to arrange for a course of instruction on the laws of health A syllabus of lessons has been drawn up by the medical officer, including air supply, water-supply, food, sunlight, cleanliness, clothing, exercise, rest, dwelling house, and the avoidance of active causes of disease. The state of the young adults of the Manchester population, as shown by the rejection of 8000 out of 11 000 would be recruits, has been noted by the Salford School Board and it seems to be making an earnest effort to do what it can to arrest the decadence that has already become so alarming A record is being taken by a committee of the board of the weight and measurement of the children at different ages and of the committee of four three are medical men. Three schools have been chosen for the inquiry as they are typical of the different classes of children coming under their care. The records are taken by the medical officer with the coöperation of the committee, but it is intended to have the teachers instructed so that they can carry out the work. The height, weight, chest measurement, and circumference of the head are taken and inquiry is being made as to there being any correlation between the physical condition of the children and their home circumstances All this is preliminary to the further consideration as to whether anything can be done, in addition to what is now done, to improve their physical condition. At present physical training is given in all the board schools in accordance with the model scheme of the Board of Education which the adult teachers have become competent by special training to carry out. It is to be hoped that with the new Education Act without neglecting the mind more attention will be given throughout the country to the bodies of the children for hitherto they have had less than they have deserved

Food Inspection in Manchester

Although from the hygienic point of view the destruction of unwholesome food is necessary yet when the tendency to rise in price that seems to prevail almost universally is considered it is deplorable that there should be so much loss year by year as is shown in the report of the market committee of the city council. Last year 176 754 pounds of meat were condemned and destroyed in Manchester. Of this enormous quantity there were 117 498 pounds of beef, 48,312 pounds of fish 31,195 pounds of shell fish, 5901 rabbits, besides hundreds of hares grouse, pheasants, quails, poultry, &c. With the exception of 913 pounds of meat, 1078 pounds of fish, and some tins of preserved food stuffs which were exposed for sale all was surrendered after being condemned by the inspectors The meat and fish were discovered at the wholesale and retail markets, at railway stations, shops, on hawkers' carts, at farms, in the cold air stores, and other places. The hawkers' carts, however, were not bad by comparison. The great bulk of the meat was condemned at the abattoirs and markets Of the rabbits and game condemned at the Smithfield Market the former are the more numerous, as one would expect Black currants seem to bear transport and to keep worse than most other fruits, nearly 1000 boxes having to be destroyed. It seems curious that no mention is made of partridges, though quails and ortolans (93) pigeons, turkeys, &c., come in for condemnation. In addition to the inspection of the abattoirs and markets, 3916 visits were made to the private slaughter-houses, of which there are still a number in Manchester, 14 059 carcasses were examined, and 5829 visits were made to shops in the poorer districts of the city This is a very brief and imperfect sketch of the work done by the inspectors, but enough has been said to show that supply and demand do not adjust themselves automatically and that food preservation and distribution still leave room for improvement and better organisation. That it would be worth while to do what can be done to mend matters is evident from the fact that all this waste takes place in one town, with a population of less than 600 000 and that there is no reason to suppose that Manchester differs from other parts of the country in being careless and improvident. The loss of food that must be going on in a population of about 41,000,000 is deserving of more attention than we often give to it, and perhaps none the less so because it must be difficult to prevent.

Legacy to the Salford Hospital.

The late Mr William Hatton of Manchester has by his will left a sum of £6500 to the Salford Royal Infirmary

A Presentation Portrait

A number of friends have subscribed for a portrait of Mr E S Heywood who was for many years the chairman of the Royal Infirmary Board. It will be presented to the infirmary and hung in the board room It has been painted by Mr Ralph Peacock and is described 'as a characteristic and faithful likeness of the sitter and as a singularly vigorous and attractive painting' Mr Heywood, it may be remembered, together with most other members of such assistance. Others, on the contrary, fancy that they have a right to call on their medical officer for the most trivial ailment and are constantly coming for medicine when there is really nothing the matter with them. Such clubs do not pay whatever the amount of their subscription

Some time ago an insurance company attempted to establish itself at Cardiff and it introduced a medical practitioner This company employed a woman canvasser who went from house to house extolling the advantages of insuring and the virtues of the medical officer who was to attend all those persons who took out a policy This woman canvassed the patients of different practitioners. One well established practitioner told me that some of his patients asked him whether he kept a club The advantages of joining a medical aid association had, they said, been explained to them by a lady who had called They felt that, in justice to themselves, they ought to join some such organisation, but rather than subscribe for the medical man whom the lady canvasser had mentioned to them they would prefer to join a club with which my informant might be connected In other words, they did not wish to change their medical adviser, but they preferred paying *1d* per week instead of the usual fees as private patients. As most of these people can afford to pay the usual fees it will be seen what a demoralising effect such canvassing must have upon those who are ever anxiously hunting in all directions for cheapness They can pay for medical attendance, but they are nevertheless only in receipt of modest incomes and would not at all object to reduce the cost of medical attendance just as they would with equal eagerness gladly accept free seats at the theatre Of course, such persons are advised by their usual medical attendants not to join any club or medical aid organisation, but such advice would have much more force if it could be shown that the medical practitioners of the town were organised against the encroachments of clubs or insurance companies and their lady canvassers. Fortunately, however, for the practitioners of Cardiff the medical officer whom the insurance company had introduced into the town sold his practice It was bought by a medical man who, to his credit be it said, disapproved of the whole system, so that the lady canvasser and the insurance company disappeared from the field

From Cardiff I went to Aberdare where I found that exceptionally favourable conditions prevailed. The payment at the collieries in this valley and in the Rhondda valley is based on what is denominated the "poundage" system Instead of paying a fixed sum per week the charge is, like the income-tax, so much in the pound This is a very fair arrangement, because those who have low wages pay little and those who have better wages pay a proportionately larger sum. The only difficulty is to agree as to what that proportion shall be Fortunately for the medical practitioners the miners have from the first shown no disposition to drive a hard bargain. I appears that at Ynysybwl, Abercynon, Treharris, Merthyr Vale, in Monmouthshire, and in the whole of the Rhondda Valley, the miners pay *3d* in the pound for medical attendance. Nor is this a recent arrangement due to special endeavours on the part of the medical profession, for the custom has prevailed now for more than half a century All that has been necessary of recent years has been to extend this system to a wider area. Therefore meetings of local practitioners were held during 1899 at Aberdare and the Aberdare Valley Colliery Surgeons Society was formed—as a branch of the Medico Ethical Society mentioned above—with Dr E J Trevor Jones as the secretary All the local practitioners, with only two exceptions, joined. These two practitioners are not opposed to the movement but their practice is of a different nature. They deal with the town rather than with the colliery population, but the clubs formed by artisans, shop assistants, small tradesmen, &c, were affected by the example of the *colliers*, and instead of paying from 8*s* 8*d* to 13*s* per annum per family, as at Cardiff and Swansea these clubs pay £1 1*s* per annum and this directly to their medical officer Nevertheless, the general feeling among the majority of the medical practitioners is against clubs of any description. They argue in favour of poundage and no intermediaries So much per pound should be deducted from the wages paid by the employer and forwarded directly to the medical officer selected. There is no need of committees, clubs, or other organisations

In the Aberdare district the amount thus paid was, however, only *2d* in the pound Consequently, the local practitioners, after meeting and agreeing together, gave notice and even placarded the district stating that they would not attend the colliers and their families for less than *3d* in the pound of wages received Apart from the usual arguments in regard to the increase in the cost of medical education, of qualified assistants, of drugs, instruments, &c., which apply to medical practice in all parts of the kingdom, there is the fact that with the poundage system work has sometimes to be done for nothing and this for a considerable period of time Most of the colliery surgeons, for instance, experienced very severe losses during the great strike of the South Wales miners As the miners then received no wages there was no payment for medical attendance, but the medical practitioners had to continue to pay for their drugs, for their medical assistants, and for their usual domestic necessaries It required some years of prosperity to recoup this loss Then the local practitioners do more under the poundage system than under the club system For instance, they provide cod liver oil, castor oil, and linseed meal, and, what is more important, attend confinements without extra charge The latter, it is pointed out, is a great benefit and the miner need not endanger the life of his wife during this critical period by the fear of having to pay an extra fee. When the poundage was *2d* this did not include midwifery cases but the medical officers were really called in for confinements and found it a matter of difficulty to obtain extra fees for such attendance. It would, therefore, they urged, be better for the miners as well as for the medical practitioners if everything was included in the one payment and so that this might be done they proposed that the payment should be raised from *2d* to *3d* in the pound. After some discussion this proposal was accepted by the miners, so that all parties are satisfied and there is no grievance on that score Whatever difference of opinion may exist now relates rather to the distribution of the money paid than to the amount that should be paid. It may be said that the miners, generally speaking, do not begrudge the *3d* in the pound which they pay, and on the other hand, the medical practitioners recognise that in the circumstances this is a sufficient payment But some miners have remarked that they do not like the manner in which newly qualified assistants are employed They come down among the miners, the latter become acquainted with them and learn to like them, and then just as they begin to appreciate each other the assistant disappears and some other young gentleman comes to take his place. The miners have wondered whether there might not be a little bit of sweating going on within the ranks of the medical profession itself and whether in the employment of qualified assistants there is not a tendency to get rid as soon as possible of the more able and popular of these assistants for fear that they might settle down as independent practitioners in the district Ought we, said the miners, to pay our *3d* per week in such a manner as to create a monopoly of medical practice?

The other side of this question is ably represented by Mr Evan Jones and his son, Dr E. J Trevor Jones of Aberdare. Mr Evan Jones from the first has laid down that it is better to pay £1000 a year to one or two medical practitioners of the very highest standing who would employ qualified assistants than to pay £500 separately to eight practitioners. The eight practitioners at £500 a year each cannot have all the instruments, operating tables, and means of treatment that can be provided at one central and better equipped surgery It must be remembered, also, that in this neighbourhood there is no general hospital available, but only a small private cottage hospital supported mainly by the Marquis of Bute Yet fearful accidents occasionally occur in the mines which necessitate the most difficult operations Mr Evan Jones urges that considering the great responsibility this involved there should be one chief surgeon and no other The miners should be free to elect whom they pleased, but once elected his authority should be undivided If many medical officers are appointed they can have but small incomes and will be too poor to secure proper assistants and to undertake every sort of work. They must therefore send the more serious cases to the hospitals and these are too far away Mr Evan Jones and Dr Trevor Jones have between them some 10 000 miners on their list and they employ six qualified assistants. Also they can fall back upon the cottage hospital established by the Marquis of Bute This, then is in itself a huge organisation and it is maintained that this sort of collective medical combination gives better results than the splitting up of the work into *des moyens fragiles*) By using a simple apparatus he had been able to exercise traction upon sutured patellæ by means of weights. In a patella sutured in the ordinary way a weight of 43 kilogrammes brought about a slight separation of the fragments, while a weight of 70 kilogrammes separated the fragments by one centimetre. When the broken patella was united by the wire being made to run around the fragments (*avec cerclage*) six kilogrammes brought about a slight separation and 20 kilogrammes a separation of one centimetre. M. Quénu accordingly was of opinion that flexion is a dangerous movement in a case of fractured patella and that a patient who has fractured his patella should take the greatest care not to walk too soon, for a simple movement or flexion exerts a tractive force upon the fragments equal to a weight of 100 kilogrammes Finally M. Quénu brought before the society a special method of suture of his own which he termed ‘ transverse suture." The wire is passed through both fragments transversely in the shape of a U This method gives a firmer union than "*cerclage*," but one not so firm as the ordinary method. When the fragments are more in number than two, or being two only one of them is very small, the wire can be passed through the tendon in either the upper or the lower fragment, thus making a "*hemi cerclage*" and M. Quénu added that he had employed this method with success in the case of a woman, aged 63 years. M. Lucas Championniere considered that the ordinary method of suture gave the most satisfactory results. He asked whether M Quénu's results were applicable to cases of fracture in a living subject, for he had employed healthy patellæ in his experiments, whereas a patella which breaks is always in some way altered from the normal

The Alcohol Question.

I have upon previous occasions given your readers full information as to the debates upon the alcohol question which have taken place at the Academy of Medicine [1] At the meeting of the Academy held on Feb 24th a somewhat confused discussion took place between those members who were in favour of a general answer being returned to the question propounded by Parliament and those who were in favour of a definite and detailed scheme of regulations concerning alcoholic drinks. M. Laveran was of opinion that the following points should be insisted upon—that flavoured alcoholic drinks are doubly dangerous, first from the alcohol and, secondly from the essences used for flavouring Flavouring essences should be classed in the order of their toxicity The Academy should not proscribe certain flavouring agents and issue regulations only for the use of others, for it would then appear that the Academy approved of the latter In order to bring about a lessened consumption of flavoured alcoholic drinks it would seem well to lessen the number of shops where they could be bought, to tax such drinks both according to their alcoholic strength and according to the flavouring essence or essences which they contained, and finally, to appoint a special scientific commission to draw up a scale of taxation. M Magnan reminded the meeting that epileptiform convulsions had followed the use of *spirits* flavoured with the following essences, absinthe meadow sweet (*reine des pres*) *spiræa ulmaria*, and hyssop The essences derived from these three plants should be absolutely forbidden. The best means of diminishing the consumption of such drinks would be a heavy tax levied upon them Alcoholism was on the increase. After the trials of the war of 1870 the number of alcoholic cases among the patients admitted to the hospital of St. Anne was 26 per cent. A few years later this proportion fell, it then commenced to increase and at the present time the proportion was 50 per cent. For the female patients the figure was 21 per cent. M Joffroy pointed out that the Academy could not issue any regulations as to the alcoholic or essential strength of liqueurs without opening the door to the drinker saying that he drank under the ægis of the Academy All flavouring essences were dangerous and if a list of prohibited essences were published it would have to be enlarged year by year M. Bouchardat agreed with M. Laveran and thought that the classification of flavouring agents made by M Laborde was open to criticism No division for legal purposes could be drawn between the essences of anise, star anise and fennel, for chemically they were indistinguishable As for essence of noyaux, it contained only a microscopical quantity of hydrocyanic acid Many other instances could be adduced to show that the classification of the committee was premature. M Prunier agreed with M. Bouchardat and said that the idea of legislative regulation was chimerical. He would like the Academy to issue a public notice of its own which would settle the question. M Hanriot said that the public would consider any liqueur flavoured with an essence not condemned by the Academy to be one authorised by the Academy He insisted that the question of the alcohol should be dealt with on the same grounds as that of the flavouring essences. M Laborde consented to alter his report against the next meeting of the Academy, the alterations to include the opinions which had been put forward It would contain only one list of essences and they would be all prohibited. He hoped that that would be the end of the matter

Obituary

On March 9th there died quite suddenly M Louis Leblanc, a member of the Academy of Medicine He was formerly President of the Central Association of Veterinary Surgeons of France, head of the sanitary department of the Prefecture of the Seine, and practised for many years in Paris with great success as a veterinary surgeon. He made numerous reports to the Agricultural Society of France and to the committee for dealing with epizootic diseases, and these reports, together with his researches into various epidemic diseases, were considered of great value. The Academy of Medicine held him in great esteem and the general charm of his character won for him many friends

March 11th

BERLIN

(FROM OUR OWN CORRESPONDENT)

Ankylostomiasis in Prussia.

SOME anxiety is being caused by an epidemic of ankylostomiasis (*Wurmkrankheit*) which is prevailing in the mining districts of Westphalia and the Rhine Province. The ankylostomum duodenale was introduced some years ago by Italian miners and the number of patients has recently undergone an enormous increase. In the year 1896 only 107 cases were notified and in 1899 only 94, but in 1900 there were 275 in 1901 there were 1130, and in 1902 there were 1355. The disease often proves fatal and as a rule has very serious sequelæ, such an anæmia, dropsy, cachexia, and sometimes amaurosis. The mining population are therefore in something like a state of panic and the Socialist party is demanding that the Imperial Government should make more liberal grants of money for the purpose of combating the disease. A commission under Professor Loebker, the chief medical officer to the miners' hospital at Bochum, has been sent to Hungary, where the disease was prevalent some years ago, for the purpose of gaining an acquaintance with the methods adopted by the local authorities there. It is stated that the number of patients is exceptionally great in the mines where the air temperature is high and that the quality of the water used for sprinkling is a matter of importance, for in the mines where water of good quality is supplied the disease is less prevalent than in those where the ground water is used. It has therefore been suggested that the sprinkling of the mines should be quite discontinued until the epidemic has ceased.

Post-graduate Instruction Free of Charge

Post-graduate study has been much extended during recent years and has undergone various developments which are in the interest of the medical profession. Post-graduate courses of instruction for which fees had to be paid have for a long time been a feature of almost every German university, but as they were held only during the university vacations and were rather expensive the attendance was not large and consisted chiefly of medical men who could afford to leave their practices for several weeks. Civilian medical men therefore felt themselves to be placed at a disadvantage as compared with the medical officers of the army who had the benefit of post-graduate instruction provided for them free of charge by the army medical department, and the civilians have long been desirous that similar facilities should be open to them. The first step in this direction was taken in the year 1900 when a series of lectures on tuberculosis and its modern treatment were delivered in Berlin, chiefly with a view the board, resigned his position when by the vote of the trustees it was decided not to rebuild the infirmary on the Piccadilly site. It is well that the infirmary should possess this memorial of one who so long and faithfully rendered valuable and ungrudging service "to the cause of Manchester's great charity"

New Infirmary at Stockport

The Stockport guardians yesterday decided on the erection at Stepping Hill of the new infirmary The Local Government Board has approved of the plans and sanctioned the borrowing of £44,000 in order that the building may be proceeded with

March 10th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Public Health Matters in Barry

THE annual health report of the urban district of Barry is of interest from the fact that the district council has displayed commendable zeal in providing the town with such necessary equipments as a bountiful water supply, a complete sewerage system, a refuse destructor, public slaughter houses, and an isolation hospital The addition of a separate small pox hospital is strongly urged by the medical officer of health (Mr George Neale) and with the erection of this very desirable institution the town of Barry will stand as an example not only to Welsh towns but to many in England A local Act, passed in 1896, contains important provisions requiring the occupiers of laundries and dairymen to furnish the medical officer of health in certain cases with a list of customers and requiring dairymen to furnish a list of the sources of their milk supply and also to notify cases of infectious disease occurring among their servants. The population of Barry which was 500 in the year 1881 is now estimated at 27,507 The birth rate in 1902 was 39 2 per 1000, the death rate was 11 9 per 1000 and the infantile mortality rate was equal to 103 per 1000 births.

Notification of Pulmonary Tuberculosis in Cardiff

In his report for the fourth quarter of 1902 the medical officer of health of Cardiff (Dr E. Walford) states that he received 44 notification certificates of cases of pulmonary tuberculosis and that 50 deaths were registered from the disease during the quarter It would appear, therefore that only a small proportion of the cases come to the notice of the health department. The health committee has decided to engage the services of a female sanitary inspector or health visitor whose duty it will be to visit and to inspect the houses in which consumptive persons reside

Merthyr General Hospital

In the autumn of 1902 Sir William Thomas Lewis, Bart, offered to build a children's ward in connexion with the Merthyr General Hospital on condition that certain additions were made to the men's ward, the cost of which, amounting to £1000, should be borne by the governors of the hospital A shilling fund was at once inaugurated by the high bailiff of the town (Mr Cornelius Biddle, L R.C P Lond, M R.C S Eng) and has accumulated £500, while nearly £500 have been subscribed by the colliers and ironworkers of the district. When the contemplated additions are completed the number of beds available will be increased from 30 to 50 and an additional annual income of £1000 will be required Since the establishment of the hospital in 1887 the managers have kept the expenditure well below the income and at the end of 1902 had a balance of £250

Royal West of England Sanatorium, Weston-super Mare

The annual meeting of the subscribers to this convalescent home was held on Feb 28th The medical report stated that during the first four months of 1902 no patients were received at the sanatorium owing to the remodelling of the drainage system which had been carried out at a cost of about £2000 The patients admitted during the remaining eight months numbered 1668 (865 [illegible] and 803 women) 6330 warm sea baths were taken [illegible] the patients The financial statement showed that the [illegible]ceipts for the year amounted to £3092 and the or[illegible]ry expenditure to £3090

Death of the Librarian of the Royal College of Physicians of Edinburgh

By the death of Mr J Mathieson Shaw, M.A., the Royal College of Physicians of Edinburgh has lost a valuable and esteemed official and the Fellows one who was ever ready to help them in their literary investigations He had a good knowledge of modern languages and although not a medical man had an excellent acquaintance with medical literature He has left funds to found a lectureship to be called the Mathieson Shaw Lectureship, the object of which is to bring before medical practitioners and students of medicine the most recent advances and developments in the science of medicine and allied sciences. The fund is vested in the President and Council of the College.

The Morison Lectures of the Royal College of Physicians of Edinburgh.

Dr G A. Gibson delivered the second series of the Morison Lectures last week in the hall of the College on Monday, Wednesday, and Friday The lectures were devoted to the motor affections of the circulation He dealt with the nervous supply and the causes of the heart's pulsation. He considered the disturbances of cardiac movements under rate, rhythm, and force. The remainder of the first lecture was devoted to disturbances of rate The second lecture dealt with disturbances of rhythm, while the third dealt with alterations of force. The lectures were well attended and the lecturer gave a clear and pleasant exposition of the facts and theories bearing upon the subject with which he dealt.

Sir William Muir

On March 5th Sir William Muir was presented with an illuminated address from the students of the University of Edinburgh on the occasion of his retiring from the Principalship of the University The presentation took place in the McEwan Hall and was largely attended.

Small-pox in Dublin

THERE are now 16 small pox patients in Dublin, one being a student of Trinity College. The patients are all being treated in the corporation isolation hospital and one death from the disease occurred there on March 8th

The Nomenclature of Disease

Dr Ninian McIntire Falkiner, President of the Section of State Medicine of the Royal Academy of Medicine in Ireland briefly reviewed the Nomenclature of Diseases and Causes of Death from the period of William Cullen of Edinburgh up to the year 1901 at a meeting of the section held on Feb 20th. At this date Dr J F W Tatham's modification of the nomenclature of diseases (1896) was adopted for the official reports on vital statistics for these countries. In the course of his address Dr Falkiner appealed to the medical profession to consider the importance of giving a well defined and accurate "cause of death" when framing the certificate, as it was on this testimony, and this testimony alone, that the value of the medical statistics of the nation depended After the conclusion of the address the following motion was proposed by Dr Bewley, seconded by Dr Parsons, and carried unanimously —

> That in the opinion of the Section of State Medicine of the Royal Academy of Medicine in Ireland it is advisable that the department of the Registrar General of Ireland should be represented on the Nomenclature of Diseases Committee at present sitting in London.

Suture of the Patella

AT the meeting of the Society of Surgery held on Feb. 18th M Quénu gave an account of some researches which he had made into ordinary methods of suture of the patella These methods he affirmed had not much inherent strength ([illegible]

Obituary.

WILLIAM HENRY CROSSE, M.D. DURH., M.R.C.S. ENG., L.F.P.S. GLASG., L.S.A.

LATE PRINCIPAL MEDICAL OFFICER, ROYAL NIGER COMPANY.

It is with deep regret that we record the death of Dr. W. H. Crosse, late principal medical officer of the Royal Niger Company, which took place at his residence, 37, Albemarle-street, W., on Feb. 24th. For many years past he had been in indifferent health, advancing emphysema, chronic bronchitis, an enormously hypertrophied spleen, and never absent œdema of the legs—souvenirs of his nine years' sojourn on the West Coast of Africa—being among the factors that rendered the latter years of his life a veritable battle against Atropos. The attack of bronchitis which proved fatal began on Feb. 14th and, in spite of careful nursing and the ministrations of his friends, Dr. W. Hale White, Mr. Charters J. Symonds, and Mr. E. Reynolds Ray, rapidly overpowered him. Increasing dyspnœa, only temporarily relieved by a copious venesection, rendered his sufferings terrible to witness. This was followed by three or four days' complete unconsciousness and the end came on Tuesday morning, Feb. 24th.

The son of the Rev. Marlborough Crosse, William Henry Crosse was born in Norfolk in 1858. He entered at Guy's Hospital as a student in 1878, passing out three years later with the L.S.A. qualification, to engage in general practice in Cubitt Town, Isle of Dogs. Here he rapidly built up an extensive and lucrative connexion, which, however, he relinquished five years later in order to return to Guy's Hospital to obtain further experience and to take out additional qualifications. In 1886, having obtained the Membership of the Royal College of Surgeons, he joined the Royal Niger Company of England and proceeded to the West Coast as its medical officer. Here he remained on active service for a period of nine years, taking part in all the expeditions (for which he received the Company's active service medal) and permitting himself but very little leave, although he suffered severely from malaria and had at least three attacks of blackwater fever. His duties during this time were many and diverse and as he often jokingly remarked, "W. H. C. embodied in himself the various offices of principal medical officer, governor of the gaol, chief justice of the peace, agent, machine gunner, and, *in posse* at any rate, lord high executioner." All along the coast he made a name for himself that is remembered with love and affection, men recognising him as a friend and brother and one to whom they could turn for sound advice and ready help. In 1895 Dr. Crosse returned to London, when the urgent representations of his friends persuaded him to relinquish his post (the directors of the Niger Company, however, retaining him as their London medical adviser) and to settle in practice in London, which he did first in Half Moon-street and then in Dover-street, Piccadilly, from which latter address he only moved last year to the house in Albemarle-street which he occupied at the time of his death.

His work-a-day habits were so methodical that in spite of failing health the cares and worries of practice were insufficient to occupy his mind completely. Hence his restless and indomitable energy and almost boyish enthusiasm prompted him again to turn to preliminary studies and hospital work, with the result that in 1900 he took the M.D. degree of the University of Durham. Of Dr. Crosse it might truly be said that he was always a student and his was a familiar figure not only in the post-mortem rooms but also in the laboratories of Guy's and Charing cross Hospitals, where his keen interest and extensive acquaintance with the clinical aspect of malaria and other tropical diseases stimulated him to examine critically the many diagnostic aids advocated from time to time by many research workers. He was a recognised authority on blackwater or hæmoglobinuric fever and his contributions on this disease to the Pathological and Epidemiological Societies were of real importance and practical value. The paper read by him before the Epidemiological Society was published in THE LANCET of March 25th, p. 821, and April 1st, 1899, p. 885, while he contributed another admirable paper on the Histology and Prevention of Blackwater Fever to our columns which, with a coloured illustration, appeared in THE LANCET of Jan. 6th, 1900, p. 11. His death at the comparatively early age of 45 years leaves a void that, so far as his intimate friends are concerned, can never be filled.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examination and conformed to the by-laws have been admitted Members of the College:—

Ernest Beadon Dixon Adams, St. Bartholomew's Hospital; William Munro Anderson, L.D.S. Eng., Charing Cross Hospital; Ernest Edward Argles, St. Mary's Hospital; Walter Seymour Armstrong, St. George's Hospital; Oliver Francis Haynes Atkey, King's College Hospital; George Washington Badgerow, M.B. Toronto, Toronto University and University College Hospital; Frederic Barker, Medical Department, University of Birmingham; Charles John Battle, St. Thomas's Hospital; Kenneth Harold Beverley, University College and Royal Infirmary, Bristol; Frederick Michael Bishop, St. Bartholomew's Hospital; William Frederick Box, Guy's Hospital; David Bridges, Charing Cross Hospital; Henry Neville Burroughes, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Arthur Robertson Brailey, B.A. Camb., and Stanley Child, B.A. Camb., Cambridge University and Guy's Hospital; Norman Carpmael, St. Thomas's Hospital; Victor Albert Chatelain, London Hospital; William Henchman Cole, Guy's Hospital; Herbert Ernest Corbin, B.Sc. Lond., St. Mary's Hospital; Philip Claude Tresilian Davy, University College Hospital; William Henry Dickinson, Cambridge University, Liverpool, and St. George's Hospital; Robert Donald, M.A., B.Sc. New Zeal., *University of New Zealand* and *London* Hospital; Norman Edwin Dunkerton, King's College Hospital; Daniel Cyril Evans, University College, Cardiff, and St. Bartholomew's Hospital; Francis William Fawssett, Guy's Hospital; Charles Breame Fowler, Aberdeen University and Charing Cross Hospital; John Douglas Hope Freshwater, Cambridge University and St. George's Hospital; William Thomas Frizzell, M.B. Toronto, Toronto University and University College Hospital; George Brittan Gill, Bristol, Durham, and Westminster Hospital; Walter Leigh Mackinnon Goldie, St. Mary's Hospital; Peter Gow, University of New Zealand and Middlesex Hospital; Archibald Montague Henry Gray, University College Hospital; Thomas Guthrie and Walter Lidwell Harnett, B.A. Camb., Cambridge University and St. Thomas's Hospital; Gustav Hamel, C.V.O., M.D. Bern, Kiel, Berlin and Bern Universities; Arthur Francis Hamilton and Thomas Henry Harker, St. Bartholomew's Hospital; Philip William Hamond, Guy's Hospital; William Trengweath Harris, L.S.A. Lond., and Lionel Swinton Hooper, St. Thomas's Hospital; Norman George Harry and Arthur George Harvey, Cambridge University and Middlesex Hospital; Henry William John Hawthorn, L.D.S. Eng., Medical Department, Birmingham University; Geoffrey Seccombe Het, University College Hospital; Thomas Lewis Ingram, Cambridge University and London Hospital; William James Deacon Inness, St. Mary's Hospital; Alfred William Iredell, Guy's Hospital; Ivor Davenport Jones, Middlesex Hospital; Henry Michael Joseph, B.A. Camb., B.Sc. Lond., Cambridge University and Charing Cross Hospital; Rustamjee Maneckjee Kalapesi, L.M. & S. Bombay, Grant Medical College, Bombay; Henry Wynyard Kaye, B.A. Oxon., Oxford University and London Hospital; Kenneth Harrison Alloc Kellie, Cambridge University and St. George's Hospital; Ernest Henry Kenderdine, Medical Department, University of Birmingham; Henry Ratcliffe Kidner, B.Sc. Lond., St. Bartholomew's Hospital; Ronald Outram Lee, B.A. Cantab., Cambridge University and Middlesex Hospital; Robert Robinson Lewis, Middlesex Hospital; Allan Douglas Low and Nelson Low, St. Mary's Hospital; Godfrey Holland Latham, Charles de Zouche Marshall, and Albert Francis Miskin, St. Thomas's Hospital; Samuel Harvey McCoy, B.A., M.B. Toronto, Toronto University; Henry Richmond Minkley, St. Mary's Hospital; Robert Vernon Gerard Monckton, St. Bartholomew's Hospital; Archibald Trevor Moon, London Hospital; David Morrow, L.S.A. Lond., Queen's College, Belfast, and Middlesex Hospital; Stanley Parkes Mummery, L.D.S. Eng., St. George Hospital; Henry Bailey Mylvaganam, L.M. & S. Ceylon, Ceylon Medical College and London Hospital; John Sherwood New, University College Hospital; Eugene Joseph O'Neill, M.B., Ch.B. New Zeal., Otago University, New Zealand; Edward Daniel Parsons, St. Thomas's Hospital; Charles Burnage Penny, Guy's Hospital; Arthur Pick, M.D. Germany, M.D. Austria, Breslau University; Egerton Llewellyn Pope, B.A. Kingston, Canada, M.D., C.M. McGill University of McGill College, Montreal, and University College Hospital; James Houston Porter, London Hospital; John Llewelyn Pritchard, Royal Infirmary, Liverpool, and Glasgow; George Herbert Richard, St. Mary's Hospital; Edmund Arthur Roberts, King's College Hospital; Lorne Forbes Robertson, B.A., M.D., C.M. McGill University of McGill College, Montreal; John Norman Robins, M.A. Camb., Cambridge University and London Hospital; Thomas Rose, Middlesex Hospital; Christopher Wilfred Sharpley, Yorkshire College and General Infirmary, Leeds; Walter Stansfield, Owens College and Royal Infirmary, Manchester; James Batson Stephens, St. Mary's Hospital; Edward Franz Adolf Schamer, M.D. Leipzig, Leipzig University; Walter Mersh Strong, M.A. Camb., Cambridge University and St. Thomas's Hospital; Leonard Robert Tosswill, St. Bartholomew's Hospital and Devon and Exeter Hospital; Eugene Dunbar Townroe, St. George's Hospital; Charles William Turner, Durham University, Owens College, and Royal Infirmary, Manchester; John Charles Veneoski, M.D., B.S. Durh., Durham University, St. George's, and University College Hospital; Vernon Montague Wallis, Guy's Hospital; John Wells, Medical Department, University of Birmingham; Alfred Landon Walter Whitehouse, L.D.S. Eng., Westminster Hospital; Fielding Charles Whitmore, Dublin University College and Royal Infirmary, Bristol; Charles William Tuthill Woods, Cambridge University and St. George's Hospital; and Harry George Keith Young, B.A. Camb., Cambridge University and Middlesex Hospital.

to popularise and support the movement in favour of sanatoriums These lectures were a great success, so that in the autumn another series were delivered on venereal diseases No fees were payable for attendance on these lectures, which were delivered under the auspices of the Government by professors, *privat docents*, and other specialists About the same time similar lectures were delivered in various universities and some of the larger towns and everywhere met with the approval of the medical profession. In 1901 a central committee was formed in Berlin for the purpose of organising gratuitous post-graduate courses on a greater scale throughout Prussia. This committee, of which Professor von Bergmann is the chairman has now instituted such courses in 23 towns and has, moreover, acquired a collection of medical books, tables, pathological specimens, microscopes, and instruments to be used in connexion with the lectures and especially to be lent to the local committees in small places where such means of instruction are not sufficiently available This collection was exhibited a few months ago in Berlin and is well supplied with the necessary material, a good deal of which has been presented to the committee by hospitals, clinics, and other medical institutions. A building will be erected in Berlin to serve as the headquarters of the organisation in Prussia, it will contain lecture rooms, laboratories, rooms for the storage of the collection of objects already mentioned, and offices for various purposes In memory of the late Empress Frederick, who always took a great interest in the subject of post-graduate instruction for medical men the building will be called the Empress Frederick House for Post graduate Training The Emperor recently received Professor von Bergmann, the chairman of the committee, the Minister of Public Instruction being also present and His Majesty then expressed complete approval of the plans of the committee

March 9th

EGYPT

(FROM OUR OWN CORRESPONDENT)

Acute Febrile Jaundice (? Weil's Disease)

DR VALASSOPOULO of Alexandria prepared an interesting report upon this disease for the Cairo Medical Congress which he has since published. The disease is practically never seen in Cairo and most other parts of Egypt, but it is found every year in Alexandria either as an epidemic in certain parts of the town or as producing sporadic cases It begins in the month of April and disappears about September The specific organism of relapsing fever (spirochæta Obermeieri) has never been found in these cases, and though it is obvious that the disease belongs to the infectious group and must be microbic, the specific microorganism has not yet been discovered While mentioning other microbes Dr Valassopoulo only cursorily refers to Jaeger's bacillus proteus fluorescens He wishes the disease to be called "typhus bilieux" or "ictère infectieux fébrile." He believes that the fever is undoubtedly caused by the bad drainage system of Alexandria, and points out that the disease was unknown in that city until 1870, one year after the paving and drainage of the streets was begun, also that the quarters of the town most infected are exactly the lowest, where the drains remain full of sewage because there is not sufficient fall, and in the summer months because there is no rain to flush them It is noteworthy that the fever has disappeared from one small street since the drain has been changed for the better and also that the fever is never found in the suburbs of the town which are neither paved nor drained. It is suggested that flies may convey the poison from the drains to the surface soil and to food. Dr Valassopoulo believes, after studying the fever for 25 years that it is not contagious for though treated in the general wards of the hospital it has never spread to other patients or to nurses As it is generally stated in European text-books that the disease is confined to workmen and butchers I may mention that in Alexandria there have been several cases among bankers, merchants, lawyers and medical men. The statistics at the Greek Hospital for the last ten years show that only nine women but 144 men were attacked, while during the whole 25 years not a single child under 15 years had the disease, it is also rare after the age of 40 years. Dr Valassopoulo firmly believes that the disease is not the same as the "bilious typhoid" which Griesinger described in Cairo, for this seems to have been a form of relapsing fever, but that the Ale andria fever is exactly analogous to that described in Europ as Weil's disease He strongly recommends the municipali of Alexandria to devote money for a proper drainage syste of the town to drive out this disease as has already bee done at Nauplia in Greece At Smyrna this disease h been known for about 100 years, but at Nauplia there only a record of a serious epidemic in 1886, when dur the space of four months 185 people were attacked out the 4500 inhabitants In both of these towns the disease believed to be due to imperfect drainage and the fever chiefly confined to the lower parts of the town where t drainage system is at its worst. The incubation of t disease must be short, for there are several cases on reco of healthy people being attacked two or three days aft they reached Alexandria. The onset is sudden and oft ushered in by rigor and rise of temperature to 102° 104° F, accompanied by vomiting, general pains, a albuminuria, with injected conjunctivæ insomnia, a enlarged painful liver The jaundice does not begin un three or four days later, the urine then diminishes rapid in quantity, and there are epistaxis, hæmatemesis, petechiæ of the skin As the patient convalesces t quantity of urine is increased to eight or even 10 pin in the 24 hours, and after the twenty first day t temperature becomes normal, the jaundice disappears, a there is no important symptom left except great weakne Very mild cases, however, begin their convalescence early as the eleventh day At the necropsy of fatal case besides dark liquid blood and general congestion everywher there are well marked petechiæ in the small intestine, colo kidney, and sometimes in other organs The mortality about 32 per cent in the Greek Hospital and probably mu more outside Death takes place between the sixth and eigh day of the disease from cardiac weakness or from uræmi Dr Kartulis of Alexandria does not believe that the bilio typhoid fever of his city is identical with Weil's disease, which he has seen cases in Germany His own statistics the mortality of the former disease are 60 per cent., whic contrasts strangely with the German mortality of from 2 to per cent in Weil's disease. Alexandria has not a comple monopoly of this interesting malady for Dr Legrand h published two cases at Suez and Dr F M Sandwith r cognised five cases in Cairo in 1899

Typhoid Fever

Sporadic cases of typhoid fever still occur every winter i Cairo and Alexandria, generally in English families where th greatest precautions are taken to prevent it The water ca hardly be the cause, but it is fair to suspect the milk suppl because the dairies are not yet under any Government supe vision Professor Chantemesse of Paris during his recen visit to Cairo drew the attention of physicians here to hi method of treating the disease by anti typhoid serum. H compared 1478 cases treated in 15 Paris hospitals during th last two years by cold bathing and ordinary symptomat treatment, which gave a mortality of 19 3 per cent., wit 186 cases treated at his hospital during the same time wit only 3 7 per cent of deaths The only difference in the treatment was that he used serum in addition to cold bathin and other means. The serum does not, however, prevent pe foration, for death occurred in three of his cases from th complication He is extremely anxious to inaugurate on necessary reform in Paris which he was pleased to find alread existing in Cairo, that typhoid fever cases should be treate in special wards and not in general wards with too careles disinfection of excreta. Dr T Courmont of Lyons claim to have discovered the bacillus of Eberth in the blood o typhoid fever patients even when the Widal reaction is no positive. In 33 cases he has now found it at times varyin from the fifth day to the twentieth day, but he has neve found it in any patient later than the third week. Th method is simplicity itself, a culture is made of from tw to four cubic centimetres of suspected blood in from 300 t 500 cubic centimetres of broth. A positive report can generally be given in 24 or 48 hours, but it is not safe to giv a negative report until the fifth day of the culture.

Antipyrin.

Dr Gonzalez Alvarez of Madrid praises highly antipyri for diseases in hot countries and suggests that it should be tried to kill worms in the body such as bilharzia and filaria. He insists on the harmlessness of large doses such as 120 grains per day and states that even doses of 300 grains only produce deep sleep.

Cairo Feb 22nd

THE LONDON HOSPITAL—The general court of governors was held at the London Hospital on March 4th, when the Hon Sydney Holland presided The report stated that during the last year 13,160 in patients were treated in addition to 162,147 out-patients The number of children under 12 years of age who were treated as in patients was 3499, while 1404 Hebrews were treated as in patients with due observance of their religious scruples. The total expenditure on the maintenance and management of the hospital was £87,550, whilst the extraordinary expenditure amounted to £92 239 Of this extraordinary expenditure about £3000 constitute a certain expenditure which is sure to recur every year and therefore may be considered as ordinary expenditure, making the total of the ordinary expenditure over £90,000 The ordinary income has amounted to £65 700, and in addition there has been a grant from the King Edward's Hospital Fund of £8500, and the legacies which have been received during the year amounted to £23,641. All of these legacies had to be used to meet current expenditure. The hospital is making this year a special quinquennial appeal for funds to carry on the work during the ensuing five years. It is estimated that £167 000 more must be spent on the improvement scheme which is being carried out, and for this sum an appeal is made, whilst to place the hospital on a sound financial basis an increase of at least £25 000 per annum in ordinary subscriptions and donations is necessary Mr Ernest W Morris was appointed secretary to the governors in the room of Mr G Q Roberts who has retired.—In response to the Lord Mayor's appeal on behalf of the hospital the following donations, among others have been received or promised The Grocers Company and the Clothworkers' Company, £1000 each , Sir Horace Brooks Marshall £262 10*s* , the Capital and Counties Bank (Limited), £250 , Messrs. Bass, Ratcliffe, and Gretton (Limited) and Messrs L and R Morley, £105 each , Messrs Clark, Wilson, and Co £10 10*s* , Messrs O Tennant, Sons, and Co , £52 10*s* , Messrs Price and Peirce, £100 , Messrs D and W Murray (Limited) and Messrs A Barsdorf and Co , £10 each , Messrs. Twiss and Brownings and Messrs. Coutts and Co £10 10*s* each , Messrs Bulloch and Co , £52 10*s* , Messrs F Giesler and Co , £10 , Messrs Jacob Waller and Co £21 , Hon. Mrs. Farquhar, £20 , Mr J A. Davis £10 10*s* , Mrs. Louisa A. Ferguson, £5 , the London and Edinburgh Shipping Company and Mr P W De Keyser £52 10*s* each , and De Keyser's Royal Hotel Company (Limited), £25. Further donations should be sent to the Lord Mayor at the Mansion House.

Parliamentary Intelligence.

HOUSE OF COMMONS

WEDNESDAY MARCH 4TH

Employment of Children Bill

The HOME SECRETARY introduced his promised Bill to make better provision for regulating the employment of children and he had the gratification of being complimented by both sides of the House In 1901 his predecessor appointed a committee to inquire into the question and the Bill, he explained is based on the recommendations of the committee. It proposes to give powers to county and borough councils to make by laws for regulating the employment of children by prescribing the age below which employment is illegal by prescribing the hours between which it is illegal and by prohibiting the employment of children in certain specified occupations which may be shown to be dangerous either to health or to morals. The by laws will not apply to children already protected in their employment by the Factory Acts or the Mines Acts or to children over 12 years of age who in pursuance of the Education Acts are wholly exempted from obligation to attend school. The Bill also gives power to make by laws for the regulation of street trading under the age of 16 years and the prohibition of such labour under the age of 11 years It will apply to Scotland as well as to England In the course of the discussion the Home Secretary was strongly urged not to allow the proposals to be whittled down.

Sale of Adulterated Butter

The text of the Bill which Mr HANBURY introduced to amend the law with regard to the sale of adulterated butter has been printed It provides that (1) it shall be unlawful to manufacture to sell to expose for sale or to import any butter or butter mixture containing more than 20 per cent. of water and every person who manufactures sells exposes for sale or imports any butter or butter mixture which contains more than that percentage shall be liable on summary conviction to the penalties imposed by Section 4 of the Margarine Act 1887 as amended by Section 17 Subsection 2, of the Sale of Food and Drugs Act, 1899 and that (2) the provisions of the Sale of Food and Drugs Act 1875 to 1899 relating to margarine shall apply to any article to which this section applies but subject to the following provisions: (*a*) the expression "adulterated butter" shall be substituted for the expression "margarine" on any brand mark label or wrapper required by the provisions applied by this Act and for all other purposes of those provisions (*b*) section 8 of the Sale of Food and Drugs Act 1899 (which restricts the amount of butter fat in margarine) shall not apply The Bill applies to butter to which any substance has been added whereby the amount of water in the butter is increased but not to the article known as Irish salt firkin butter or to margarine as defined by the Margarine Act 1887 Any water in excess of the proportion prescribed for genuine butter by the regulations in force for the time being under Section 4 of the Sale of Food and Drugs Act 1899 which is found in any butter or butter mixture shall for the purposes of this section be deemed to be due to the addition of some substance unless it is proved to be due to the ordinary process of making butter —The Bill was very well received

THURSDAY MARCH 5TH.

Applecross Medical Officer

Mr WEIR asked the Lord Advocate, in view of the fact that applications are invited for the appointment of medical officer and vaccinator for the Applecross district of the parish of Applecross Ross shire would care be taken that the medical officer appointed possessed the Public Health Diploma required under the Public Health Act 1897?—The LORD ADVOCATE replied: No such diploma is required for the appointment in question which has already been made.

Report of Poisons Committee

Colonel LONG asked the First Lord of the Treasury whether his attention had been drawn to the report of the departmental committee of the Privy Council in Schedule A of the Pharmacy Act, 1868, and whether in view of its effect on agriculture the Government proposes to bring in a Bill to give effect to its recommendations —Mr BALFOUR replied The report is under consideration with a view to legislation at the earliest opportunity

Treatment of Harmless Lunatics

Mr HAMMOND asked the Chief Secretary to the Lord Lieutenant of Ireland having regard to the restrictions placed upon boards of guardians in Ireland in the treatment of harmless lunatics if he would favour the proposal for the assimilation of the law in Ireland to that in Scotland under which it is practicable to have these persons boarded and cared for in the homes of the peasantry —Mr WYNDHAM replied: The question of making better provision for the treatment of harmless lunatics in Ireland is receiving consideration

Uncertified Deaths

Mr CORRIE GRANT asked the Secretary of State for the Home Department whether he would state the number of uncertified deaths in England and Wales during 1897 1898, 1899 1900 and 1901, in completion of the figures given by Sir M W Ridley on May 24th 1897 —Mr AKERS-DOUGLAS replied The numbers of deaths of which the causes were not certified are as follows 1897 11 103 1898 10 441 1899 10 745 1900 11,257 and 1901 9936 The matter is dealt with on p xxix of the Registrar-General's report for 1902. The figures for 1901 represent slightly under 2 per cent of all registered deaths

Infectious Diseases in Ross and Cromarty

Mr WEIR asked the Lord Advocate in view of the fact that the report of the South western District Committee for Ross and Cromarty dated 26th July last shows that there were cases of typhoid fever and other infectious diseases in the district during the year which necessitated the closing of three public schools for periods varying from three weeks to two months whether he could now state the cause of the outbreak and what steps had been taken to prevent a recurrence of fever?—The LORD ADVOCATE replied The medical officer is unable to state the cause of the outbreak He assures the Local Government Board that the affected houses have been cleansed and disinfected as carefully as possible.

TUESDAY MARCH 10TH.

Spread of Small pox

Sir JOSEPH LEESE asked the President of the Local Government Board whether the attention of the Local Government Board had been called to the outbreak of small pox in many of the large centres of population of Lancashire and Yorkshire and to the fact that the spread of the disease from town to town had been invariably found to be caused by persons of the tramp class and whether the Board intended taking any and if so what action with the view of controlling or licensing the movements of persons of the tramp class as a precaution against the spread of small pox and other infectious diseases —Mr LONG I am quite aware of the outbreak of small pox in the districts mentioned by the hon Member I do not think that the spread of the disease from town to town has been invariably caused by persons of the class referred to but I am fully alive to the risk of diffusion of small pox by this means I am not in a position to take action of the kind contemplated in the last part of the question but I last month issued a circular letter to boards of guardians drawing attention to the danger of infection being conveyed by tramps and urging them to secure as far as practicable the vaccination or revaccination of all persons relieved in the vagrant wards and to cause a daily medical inspection of all the inmates I am also advising the sanitary authorities of the districts concerned through the medical inspectors of my department as to the adoption of all practicable precautions against the spread of small pox from this source.

Army Medical Service.

Mr BRODRICK in introducing the Army Estimates for the year made reference to the reorganisation of the Army Medical Department He congratulated the public and the service on having obtained the assistance of those distinguished civilian medical and surgical experts who constituted the Advisory Board and stated that he had placed upon this board the responsibility of selecting candidates for the Royal Army Medical Corps of examining the condition of home and foreign hospitals and of carrying out the great changes which were proposed in the Army Medical Department. At the first examination for the Royal Army Medical Corps there were three times as many candidates as vacancies and the candidates he was informed, were of a very high class The right hon gentleman also explained the steps which have been taken for establishing and carrying on the Medical Staff College at Millbank and for encouraging members of the Royal Army Medical Corps to engage in special work, particularly sanitary work He said that courses of lectures on sanitation had been started at Woolwich at Sandhurst and at the staff colleges in the various districts. The principle of selection by merit had been established in the Royal Army Medical Corps. Names, he said, were submitted to the Advisory Board

University of Cambridge —At the Congregation held on March 7th the following degrees were conferred —

M D—L C P Phillips Caius

M.B and B C—J F H Dally St John s and J M Twentyman Christ s

M B—J W Wharton St John s and T St C Smith Trinity Hall

Dr Anningson and Professor Sims Woodhead have been appointed University delegates to the Congress of the Royal Institute of Public Health to be held at Liverpool in July —Dr S West has been appointed an examiner in medicine in the place of Professor Greenfield and Mr G E Wherry an examiner in surgery in the place of Mr E B Owen.

Royal College of Physicians of Ireland —At a meeting of the President and Fellows of the College held on March 6th Mr Owen Gilmore, L R.C P & S Edin., &c , was admitted a Licentiate in Midwifery of the College.

Royal Institution —The Friday evening discourse at the Royal Institution on March 6th was delivered by Professor J G McKendrick of Glasgow University, the subject being Studies in Experimental Phonetics A short account was given of the various methods that have been employed for obtaining graphic records of sounds, especially the Edison phonograph, and curves traced on long slips of glass by such means were shown on the screen as lantern pictures. Professor McKendrick said that the vowels owed their special quality to the resonance of the primary laryngeal tone creating mouth tones which were added to the laryngeal tone or might even overpower it. In the production of consonantal sounds such as *p*, *b*, or *m*, the form of the vowel curve, whatever the vowel might be, was modified by the manner in which the lips were either opened or closed in uttering the various sounds

The Carnegie Trust for the Universities of Scotland —The second annual meeting of the Carnegie trust was held on Feb 23rd at the Westminster Palace Hotel London, Lord Elgin presiding The report of the executive committee for the year 1902 stated that in August, 1902, the King had been pleased to grant a royal charter of incorporation whereby ' the Carnegie trustees for the Universities of Scotland" were constituted one body corporate and politic. Orders had been given for the making of a common seal to be used as the charity directed At a meeting of trustees held in July, 1902 a recommendation of the executive committee was adopted, in consideration of which the executive committee would during the season 1902 03 continue to accept the examinations qualifying for admission to the various Faculties at the universities with a view to graduation, but after due notice publicly given an approximately uniform test of preliminary education would be applied to all beneficiaries of the Carnegie trust at as early a date as possible The committee approved and adopted a scheme of allocation for five years of an annual grant of £40,000 as from Jan. 1st, 1903 The scheme, which is described in Appendix A of the report, besides making a contribution of £100,000 to buildings and permanent equipment and of £20,000 to libraries, would at the close of the period of five years have increased the resources for teaching in the four universities by permanent endowments amounting to £70,500, while at the same time it would have made during those five years an addition of £1900 a year to the income of two of them. A common scheme dealing with the institution of scholarships, fellowships, and grants had been established, the administration of which would be retained in the hands of the committee. The nominations and applications under this scheme would be referred to an advisory board, consisting of the chairman, the four representatives of the universities and three other members of the trust. Details of the regulations for those scholarships, fellowships, and grants had now been made public With regard to the payment of fees there had been paid by the trust for the summer session 1902, the sum of £11,976 13*s* , on behalf of 1595 students, representing the fees of 4522 classes , and for the winter session 1902 03 the sum of £28,275 5*s* , on behalf of 2867 students, representing the fees of 8806 classes—making in all, for the year ending Dec. 31st, 1902, the sum of £40,251 18*s* The committee realised the danger of applicants demanding class fees without proper consideration of the number and subjects of classes applied for A student might apply for the fees of more classes than he could properly attend, or for the fees of a haphazard choice of classes which had no educational relation to each other, or, again, for the fees of re-attendance upon classes because of an unsatisfactory attendance previously The committee consequently had drawn up regulations which it hoped would place a check upon indiscriminate claims in relation to the payment of class fees More detailed information with reference to the administration of the trust is to be found in the seven appendices to the report.

The After-Care Association —The annual meeting of the members of the After Care Association, of which Princess Christian is patroness and the Earl of Meath is president, was held at the house of Sir William Church and Lady Church on March 4th The chief objects of this association are to facilitate the readmission of poor persons discharged as recovered from lunatic asylums into social life (1) by obtaining for them when needful an interval of change of scene and air under proper care and supervision , (2) by giving them grants of money and clothing , and (3) by assisting them to obtain suitable employment. The annual report stated that the work of the association had again been most encouraging During the past 12 months there had been 221 cases (149 those of women and 72 those of men) before the council, whereas in 1901 the number was 214 The income had increased to £772, but an appeal was made for increased funds to meet increased weekly payments for maintenance

The Training of Plumbers —An indenture or agreement of apprenticeship framed by the Plumbers' Apprenticeship Board of London has been adopted in substance by the National Association of Master Plumbers and the United Operative Plumbers' Association of Great Britain and Ireland as well as by the London Master Builders' Association The material points of agreement are (1) the art of sanitary plumbing taught under the indenture is defined as "technical knowledge of water fittings and other sanitary appliances and skill to construct and adjust the same in such manner as to prevent the contamination of air or water in dwelling houses or other buildings by emanations from drains and sewers" , (2) the apprentice is required to attend approved evening classes of technical instruction , and (3) to attend periodical examinations in technical knowledge and workmanship during the term, the final examination qualifying for registration by the Plumbers' Company or any statutory body established for maintaining a national register of plumbers in the public interest. The form has been adapted to the requirements of Scotch law Thus, the modern method of technical training will be assimilated to the old system of apprenticeship.

Institute of Chemistry —The twenty-fifth annual general meeting of this institute was held on March 2nd, Professor John Millar Thomson, LL.D , F R S , the President, being in the chair In his address the President described how the growing appreciation of the science of analytical chemistry from the utilitarian point of view, led to the necessity for an organisation for maintaining a standard of qualification on the part of analytical and consulting chemists The real origin of the institute was a suggestion put forward in 1872 by the late Sir Edward Frankland at a dinner given to Professor Cannizzaro on his appointment as Faraday lecturer Later, in 1876, he proposed to the council of the Chemical Society that a class of Fellows to be styled Licentiates (or some analogous title) should be created for the purpose of distinguishing between competent professional chemists and those who professed an interest in chemistry as a science and not as a means of earning a livelihood The idea was not adopted, but it was decided to found a new society, the Institute of Chemistry being formally incorporated under the Companies Act on Oct. 2nd, 1877 Among those active in founding the institute were Mr Carteighe, Professor Hartley, the late Mr Frederick Manning, Mr C Tookey and the late Dr Alder Wright. Professor Thomson himself was also a keen worker for the institute in its earliest history He proceeded to relate its progress under the successive presidents Sir Edward Frankland Sir Frederick Abel, Dr William Odling, Dr James Bell, C B , Professor W A. Tilden, Dr W J, Russell, F R.S , and Dr Thomas Stevenson He dealt with the regulations as to training and examination of candidates for the associateship of the institute, showing how the standard of the requirements for membership had been steadily raised and he commented on the consequent increasing recognition of the qualifications "A I C" and "F I.C" by Government and municipal authorities and by the leaders of industry throughout the kingdom.

Notes, Short Comments, and Answers to Correspondents.

A QUESTION OF ETHICS

To the Editors of THE LANCET

SIRS,—You state that when a practitioner is called to supersede his professional brother it is his duty to ascertain that the former medical adviser has been properly informed that his services are not longer required." From the above I presume that a medical man is justified in taking on a case where another man is *at the time* in attendance, provided the patient has sent him notice that he is not longer required. May I express my utter astonishment if this is so? I have been in practice 20 years and during this time have been frequently sent for by patients whom other medical men have been attending and told that the other medical man has been written to and, in some cases, paid I have always positively declined unless I met the man in attendance in consultation and then the patient can decide whom he wishes to have. The reason I give for doing this is that we medical men are not shopkeepers or tradesmen whom the public can as they think run from one to another without us first meeting in consultation I have always been under the impression that a medical man taking on a case where another is in actual attendance without first meeting him commits a gross breach of medical etiquette. I am, Sirs yours faithfully

March 7th, 1903. A COUNTRY PRACTITIONER.

*** Our reply to our correspondent's previous letter referred to particular points in that letter It did not lay down general rules and general rules cannot be laid down to meet all conceivable situations. "A Country Practitioner's" deductions from our words are quite wrong The view which utterly astonishes him has never been expressed by us nor do we understand how a man can be at the same time in attendance" and not longer required." Of course, it is far preferable that the superseding practitioner should do so with the full approval of the previous practitioner and after a consultation with him, but sometimes these desirable circumstances cannot be obtained. It is common to find that the first medical attendant will not discuss amicably the patient's case with the second medical attendant and we wonder whether A Country Practitioner if he were the superseded practitioner would be willing to do so. Members of the medical profession have to look after the health of the public. If a patient declines absolutely to see A and asks to see B what is B to do if (1) there is no other medical attendant in the neighbourhood but himself and A, or if (2) he is assured that whether he B attends the case or not A will not be asked to attend again? In our view B must attend the patient. The situation is a regrettable one but it is B's public duty to visit the sick. Certainly he should attempt to adjust the matter amicably with A, both in the interests of the patient and of the medical profession It is good for the patient that B should be made aware of symptoms discovered by and treatment employed by A and it is good for the medical profession that there should be no bickering over such matters But if A will not meet B what is to be done? Our correspondent, in a covering letter says that he has seen books on medical etiquette taking a considerably different view to ours, but those books have not come into our hands We thoroughly approve of the high professional attitude which he takes up but we must point out to him that in certain cases the attitude is unpractical. When a patient has decided to make a change of medical attendants the situation must be dealt with as one which the patient has every right—however foolish the action—to bring about —ED L.

FRACTURED PATELLA.

To the Editors of THE LANCET

SIRS —Allow me to bring under notice a very ready and effective means of treating ordinary fractures of the patella when to resort to hooks pins or wires can only be considered meddlesome unless in severe cases or those that have been neglected with extensive inflammation or suppuration more especially in debilitated or strumous subjects where the joint requires to be opened. The quadriceps extensor femoris is relaxed in the ordinary way and the parts are disinfected, then a strip of Leicester or Johnson's plaster is taken at least one inch wide and two yards in length is fixed firmly over the head of the tibia and encircled below the knee twice then it is carried up over the external lateral ligament so as to bind down the upper and outer portion of the bone to secure the quadriceps muscle and tendons binding it down over the inner portion. Over this an ordinary gauze bandage is applied in the same way and it is passed over the cap so as to compress the injured surfaces level. The parts being thus thoroughly secured the bandage is passed over to an assistant and having at hand a piece of sheet lead already prepared—i.e. about seven inches square, the central portion carefully cut out with exactness from the opposite bone, reversed trimmed and bevelled to avoid uneven surface or projection of cut edges—this is applied to encase the cap. Again, the bandage is taken and secured by a few more turns, the back splint is put on and the operator finishes up with what bandage he has left Subsequent treatment such as lead and opium lotion, glyco-gelatin, plaster-of Paris &c. can be used without disturbance.

These accidents although rare, require very prompt treatment and vary greatly with regard to age and constitution in gravity and as all the requirements I mention can be readily carried in the surgical bag without apparent increase of bulk the means are at hand to facilitate immediate action in emergency for the relief of the patient whilst it gives both temporarily and permanently a satisfactory result, as the metal frame does not yield like leather and should not allow displacement to show deformity by ill matched ligamentous union

Of course all injuries to joints may be more or less complicated with pain, inflammation synovitis or suppuration it is therefore very necessary daily to note these conditions.

I am, Sirs, yours faithfully

Burslem Feb. 24th 1903. G T MOCKETT.

LYING ADVERTISEMENTS

A CORRESPONDENT sends us a page from *Answers* of Feb 14th 1903. The page is page i of the supplement and contains an advertisement of the usual lying type concerning an electro-galvanic belt. The advertisers are A. M. Richardson and Co They give a testimonial from Dr Archer Farr L.R.C.P L.S.A. L.F.P & S G five years Medical Officer of Health Lambeth London who writes under date Jan 2nd, 1903. Curiously enough we are unable to find Mr Archer Farr's name in the Medical Register for 1902, although it is in the Medical Directory for the current year Possibly Mr Archer Farr does not know of the use which is being made of his name. In the Medical Directory his address is given as Bath House Putney On referring to Kelly's Suburban Directory we were, however unable to find the name of Archer Farr That gentleman would do well to dissociate himself from a firm such as that of Messrs. A. M. Richardson who send out a filthy pamphlet entitled, Important Facts for Men Only"

LIFE INSURANCE OFFICES AND FEES FOR MEDICAL EXAMINATIONS

To the Editors of THE LANCET

SIRS —I should be glad if you will advise me whether it is usual or reasonable for a life assurance company to require its medical referee to make *re examinations* gratuitously Having examined a candidate and advised unfavourably against him I was called upon in a month's time to make another examination not certainly less searching than the first and I am now refused any fee for this second examination The initial fee was 10*s* 6*d*. for a £200 assurance.

I am, Sirs, yours faithfully

March 7th 1903 LIVE AND LET LIVE.

*** Assurance companies vary in their treatment of their medical referees. Seeing how tiny the fee was for the original examination we should have thought a second fee might well have been paid. There are no definite rules.—ED L.

EXPECTORATION OF A TOOTH 13 MONTHS AFTER INHALATION INTO THE LUNG

To the Editors of THE LANCET

SIRS —I have read Dr W E. Carnegie Dickson's notes on the above case in THE LANCET of Feb. 28th p 584 with great interest but think it was a great pity that the x rays were not called in to help the diagnosis even though it was thought to be a case of early phthisis because it is very probable that the true condition of affairs would by this means have been made apparent From my experience of x rays in pulmonary diseases I feel sure that if all suspicious cases were examined by the screen and then photographed pulmonary tuberculosis would be discovered in many instances before the ordinary physical signs denoted its presence and that many cases in which the stethoscope revealed only a slight amount of mischief would by this method of examination be found to be more extensively involved.

Now that early diagnosis of pulmonary tuberculosis is of such vital importance to the individual and to the community such a valuable aid to its diagnosis as the x rays should always be made use of.

I am, Sirs yours faithfully

Lincoln March 6th. STANLEY GREEN

A FORMALDEHYDE INHALER.

To the Editors of THE LANCET

SIRS —Under the above heading in THE LANCET of Feb 21st p .62, there is described a simple appliance" for the inhalation of formalin but whether it is intended for use in an institution or as an article to be used anywhere and everywhere the writer of the paragraph does not say It may be all right to sit or to lie about in the wards of a sanatorium with a zinc muzzle over the mouth and nose, but one could hardly call it "simple" if intended for wear while walking in the street. Neither is the *prescription simple*. *Surely it is scarcely* wise to put into the hands of what must often be an ignorant public a mixture which contains a fourth part pure chloroform to be used for inhaling six or seven hours a day and even at night"—unless it is with the idea of increasing the work of coroners. I quite agree with the writer that formalin is a very important aid in the treatment of pulmonary tuberculosis" and also I would add of other diseases of the lungs, but why not use it simply with water with which it is perfectly miscible? Personally I use one part formalin and two parts water and the simple inhaler I use is the glass sponge-tube of a "Godfrey's" chloride of ammonium inhaler breathing in by the for scientific merit promotion was given and every effort was being made to bring up to date the medical and surgical equipment. With regard to hospitals he proposed instead of the elaborate machinery by which different branches of the War Office had hitherto dealt with hospitals one with the building and another with the equipment to have a small committee with a civilian member of the Advisory Board and a member of the Royal Army Medical Corps in order to hand over to it, in conjunction with the Financial Secretary to the War Office the whole administration of these services in order to secure continuity and to bring the whole question as far as possible up to date. The right hon gentleman also referred to the new footing on which army nursing had been placed

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward it to THE LANCET *Office directed to the Sub-Editor not later than 9 o clock on the Thursday morning of each week, for publication in the next number*

BARCLAY W BOWIE L.R C P & S Edin D P H Vict., has been appointed Medical Officer of Health for Farnborough (Hants) Urban District Council.

BRISCOE WILLIAM THOMAS, A.B M.D M.Ch Dub has been appointed Medical Officer of Health for the Chippenham Urban District

COPE RICARDO, M R C S, L R C P Lond has been appointed House Surgeon at the Rotherham Hospital and Dispensary

CROOKS JAMES M D, C M. Toronto, L.R C S Edin., L S A. has been appointed Medical Officer of Health for Chard

DALBY AUGUSTUS WILLIAM, L R.C P L R C S Edin has been appointed Medical Officer of Health for the Frome (Somerset) Rural District Council

DUNLOP, THOMAS M.B C M Edin D P H Cantab has been appointed Medical Officer of Health for Torquay

HODLING JOHN HENRY L S A Lond. has been appointed Medical Officer of Health for the Bideford (Devon) Rural District

JOHNSON HENRY SANDFORD M.R C.P Irel, L F P S Glasg has been appointed Medical Officer of Health for the Totnes (Devon) Rural District Council

KEIR WILLIAM INGRAM F R C S L R C P Edin has been re-appointed Medical Officer of Health for Melksham Wilts

KELLY C B M. M D Lond has been appointed Certifying Surgeon under the Factory Act for the Witney District of the County of Oxford

MILES, U W N M.R C S L R C P Lond has been appointed Certifying Surgeon under the Factory Act for the Bewdley District of the County of Worcester

MURRAY JAMES L.R.C P L R C S Edin L.F P S Glasg has been appointed Certifying Surgeon under the Factory Act for the Allendale District of the County of Northumberland

PARSONS J FREDERICK M.R C S Eng L S A. Lond has been re-appointed Medical Officer of Health for the Frome (Somerset) Urban District.

SPROTT A M.B C M Glasg has been appointed Certifying Surgeon under the Factory Act for the Appleby District of the County of Westmoreland

WADE, REGINALD M R C S Eng, L S.A. Lond has been appointed Medical Officer of Health for the Highbridge (Somerset) Urban District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

ADDENBROOKE'S HOSPITAL Cambridge —Assistant House Surgeon for six months Salary at rate of £30 per annum with board lodging and washing

ALDERSHOT URBAN DISTRICT COUNCIL.—Medical Officer of Health Salary £300 per annum

BIRMINGHAM GENERAL HOSPITAL.—Assistant Obstetric Officer

BRACEBRIDGE ASYLUM near Lincoln —Junior Assistant Medical Officer (female) unmarried Salary £125 with apartments board attendance &c

BRISTOL, ROYAL VICTORIA HOMES (INEBRIATE REFORMATORY) Brentry —Superintendent. Married and total abstainer Salary £400 per annum.

BURY COUNTY BOROUGH.—Assistant to the Medical Officer of Health for six months Salary at rate of £60 per annum with board and residence

CENTRAL MIDWIVES BOARD —Secretary Salary £300 a year

DERBY BOROUGH ASYLUM.—Assistant Medical Officer Salary £120 per annum with board and washing

DUBLIN, TRINITY COLLEGE.—Professor of Anatomy

ESSEX AND COLCHESTER HOSPITAL —Honorary Physician

EVELINA HOSPITAL FOR SICK CHILDREN Southwark S E —Medical Radiographer Honorarium £25 per annum

GLASGOW EYE INFIRMARY —Resident Assistant House Surgeon Salary £75, with apartments and board

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION —Assistant House Surgeon for six months Remuneration at rate of £30 per annum with board residence, and washing

HOSPITAL FOR DISEASES OF THE SKIN Stamford street Blackfriars S E —Clinical Assistant.

HOSPITAL FOR WOMEN, Soho-square.—Clinical Assistants

HUDDERSFIELD INFIRMARY —Junior House Surgeon Salary £60 per annum with board, residence, and washing

LIVERPOOL MILL-ROAD INFIRMARY —Assistant Medical Officer unmarried Salary £120 per annum, with board and apartments.

LONDON LOCK HOSPITAL, Soho —House Surgeon Salary £80 per annum with board lodging and washing

LONDON THROAT HOSPITAL 204 Great Portland street W —House Surgeon (non resident) Honorarium at rate of £50 per annum

MANCHESTER. MONSALL FEVER HOSPITAL.—Fourth Medical Assistant Salary £100 per annum with board lodging and washing

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN Park place Cheetham Hill road —House Surgeon Salary £80 per annum with apartments and board.

MANCHESTER OWENS COLLEGE —Junior Demonstrator in Physiology Salary £100 rising to £150 per annum

METROPOLITAN HOSPITAL, Kingsland road N E.—House Physician (salary at rate of £40 per annum) House Surgeon (salary at rate of £40 per annum), Assistant House Physician (salary at rate of £20 per annum) and Assistant House Surgeon (salary at rate of £20 per annum) All tenable for six months Also an Anæsthetist Honorarium 25 guineas per annum

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC Queen square Bloomsbury —Junior House Physician. Salary £50 with board and apartments

NEW HOSPITAL FOR WOMEN Euston road —Anæsthetist (female)

NORTH EASTERN HOSPITAL FOR CHILDREN Hackney road, N E —Resident Medical Officer Salary £120 per annum with board, residence and washing

NORTH RIDING INFIRMARY Middlesborough-on Tees —Assistant House Surgeon unmarried

OXFORD WARNEFORD ASYLUM —Assistant Medical Officer Salary £100 with board &c.

PRESTON ROYAL INFIRMARY —Assistant House Surgeon Salary £60 per annum with board lodging washing &c

ROTHERHAM HOSPITAL AND DISPENSARY —Assistant House Surgeon. Salary £80 per annum

ROYAL BERKSHIRE HOSPITAL.—Assistant House Surgeon for six months. Salary £60 per annum with board lodging and washing

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST Ventnor —Assistant Resident Medical Officer unmarried. Salary £100 per annum with board and lodging

ROYAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon and Registrar unmarried for six months Salary £100 per annum with board and washing

ST GEORGE'S HOSPITAL, S W —Dental Surgeon Also Assistant Dental Surgeon

ST PETER'S HOSPITAL FOR STONE, &c. Henrietta-street Covent Garden W C —House Surgeon for six months Salary at rate of £100 a year with board lodging and washing

SAMARITAN FREE HOSPITAL FOR WOMEN Marylebone-road N W —Anæsthetist Honorarium £20 per annum. Also Clinical Assistants

SUSSEX COUNTY HOSPITAL —House Physician unmarried Salary £80 per annum with board and residence

TIVERTON, DEVONSHIRE INFIRMARY AND DISPENSARY —House Surgeon Salary £80 and all found

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE Newcastle-upon Tyne.—Lecturer on Ophthalmology

VICTORIA HOSPITAL FOR CHILDREN Tite-street Chelsea, S W —House Physician for six months Honorarium of £25 with board and lodging

WALSALL AND DISTRICT HOSPITAL.—House Surgeon unmarried Salary £100 per annum, with apartments board and laundry

WESTMINSTER GENERAL DISPENSARY —Resident Medical Officer Salary at rate of £120 per annum, with rooms gas coal, and attendance

WEST RIDING ASYLUM Wakefield.—Assistant Medical Officer Salary £140 rising to £160, with apartments board, washing and attendance.

THE Chief Inspector of Factories Home Office London S W gives notice of a vacancy as Certifying Surgeon under the *Factory* and Workshop Act at Crosshills in the West Riding of the County of York

Births, Marriages, and Deaths.

FRIDAY (20th) —MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street W C) —4 P.M. Dr H. Tilley: Clinique (Ear) 5.15 P.M. Mr T. P Legg Injuries of the Head and Neck III.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith road W) —5 P.M. Dr Reece Some Factors of Infection

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle street W) —5 P.M. Prof E A. Schäfer The Paths of Volition

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. II. of 1902, which was completed with the issue of Dec 27th, and the Title-page to the Volume, were given in THE LANCET of Jan 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18s, carriage extra.

Cases for binding the half-year's numbers are also ready Cloth, gilt lettered, price 2s., by post 2s. *3d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the *Proprietors* of THE LANCET at their Offices, 423, Strand, W C are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM.	£ s. d.	TO THE COLONIES AND ABROAD	£ s. d.
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect and do so collect from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

mouth and out by the nose, thus bathing the whole of the respiratory tract in formalin vapour Such a simple inhaler with the small end of the tube drawn out to a mouthpiece and a movable cap to fit the lower end anyone could carry in the pocket and use frequently during the day and it ought to be produced at such a price as to be within the reach of any poor person I would say always use the original brand of normal formalin prepared by the Formalin Hygienic Company as when practising in London I met with samples made by the chemists by whom they were sold the odour of which was anything but pleasant after standing a few days This I have never found with the original. A drug is sometimes condemned altogether by a bad specimen.

I am, Sirs yours faithfully

Ryde Feb 24th 1903 J MILLER

TESTIMONIALS TO PROPRIETARY MEDICINES

IN the advertising pages of the Parish Magazine of St. Botolph s Bishopsgate, appears an advertisement dealing with a preparation alleged to be prepared by Messrs John Morgan Davis and Sons The preparation is called Phosphorised Quinine and its virtues are extolled in a testimonial headed 2, Elphinston road Hastings, and signed by G C Kernot Ph D, L R C S L.S.A. Lond &c We are unable to find Mr Kernot s name in either the Medical Register or the Medical Directory If Mr Kernot be dead we consider that Messrs John Morgan Davis and Sons should supply the date of Mr Kernot s letter and if he be alive we think that he had better have his name placed on the Register and refrain from eulogising proprietary preparations

A FAIR MAID OF FEBRUARY

"FLOWERS" said Emerson, are a proud assertion that a ray of beauty outvalues all the utilities of man The lady who signs herself "Snowdrop" in the following letter which has been addressed to the medical officer of a metropolitan dispensary acts in accordance with the quotation She proudly asserts that the vulgar routine of sanitation as generally understood should give place to her crankiness. A more comical mixture of impudence and ignorance we have seldom read

"Fulham London S W
Jan 1903

At the request of your guides we write to ask you to use natural and curative agency in your Hospitals such as natural and pure diet (fruit and hot fruit drinks can eradicate disease and maintain strength) curative colours curative clothing hot baths and bathing All drugs operations impure food and drink (flesh foul fish and Alcohol) are forbidden in the spirit world therefore against GOD s laws and a healthy soul and body—Black came into the world through evil agency is against—GOD s—divine laws and is to be abolished from our earth—Your guides earnestly pray that you will help us in these important matters and at their earnest request we must tell you that all vaccinators will be punished in this or the spirit world as most disease is due to the dirt and poison of vaccine Yours faithfully

SNOWDROP

'Snowdrop s mental attitude is that of many worthy people but they are usually able to express it in a less ridiculous manner

DEGREES FOR MEDICAL PRACTITIONERS

A CORRESPONDENT writes: "I have had frequent occasions of studying the various causes which induce students to take collegiate licences instead of university degrees. In most cases I found that the college curriculum had been entered upon in entire ignorance of the relative value of licences and degrees An announcement in the *Irish Times* of Feb 26th under the heading Medical Students Guide' must continue to foster misconception in the minds of would be students The announcement referred to states that the Royal College of Surgeons in Ireland is issuing gratuitously to any one sending for it a copy of their Students Guide: How to become a Doctor' The publication is an advertisement to induce pupils to take out the licence of that body under the Irish Conjoint Board and obviously will be taken as an orthodox guide by students parents guardians and others, to the proper mode of qualifying The students forthwith in consequence may enter and pass the Conjoint preliminary examination and thus be committed to a course leading to licences instead of degrees—a course which in 99 cases out of 100 is irretraceable. Our correspondent concludes: How to become a Licentiate in Surgery would be less open to objection than that referred to if it were really necessary for the College to advertise its qualifications

A QUERY

To the Editors of THE LANCET

SIRS —Could any of your readers tell me what books are now recommended to be read for the M D, State Medicine London University, especially in Mental Physiology?

I am, Sirs yours faithfully,

March 3rd 1903 HOUSE SURGEON

COLD PRESSURE AS A TREATMENT FOR LUPUS

To the Editors of THE LANCET

SIRS,—Can any of your readers tell me if cold pressure alone has been tried as a treatment for lupus and if there is any reason why it should not be tried? I am Sirs yours faithfully

THE THREECIS PLUG

THIS is a little device supplied by the Threecis Plug Company 3, Cross lane, St Mary-at Hill, London, E.C It consists of a small sponge plug fitted with a perforated tin cover. The plug is to be fitted into the bottom of a pipe and it can be easily removed for cleaning It certainly prevents moisture from getting into the mouth but in the experience of various members of our staff to whom we submitted a plug for trial it gives the tobacco smoke an unpleasant taste. The advertisement says: The Threecis plug becomes household word to smokers as soon as they have tried it Perhaps but sometimes a household word is short, emphatic and uncomplimentary

◆

An Enquirer —The amount to be paid depends entirely upon the evidence of the value of the practice A well established practice, or a share in such where appointments are secure and competition not likely to prove damaging is worth two years purchase The purchaser of a share in a practice usually obtains a better introduction to the practice and a better guarantee that it will not decline in value than the purchaser of a whole practice

Surgeon.—As a rule medical men holding British diplomas and degrees can practise in Canada on obtaining a licence from the Provincial Medical Boards They must however be registered, and the fees vary from £2 to £20, according to the province selected

W H C—*The man is a well known money lender*

ERRATUM —The mover of the vote of thanks to Sir Michael Foster for presiding at the conference on March 3rd on the Supply of Rural Midwives was Colonel Long M P., and not Lord Camoys as reported in our account of the proceedings

The Goulstonian Lectures

ON

THEORIES OF IMMUNITY AND THEIR CLINICAL APPLICATION

Delivered before the Royal College of Physicians of London

By A. S. F. GRUNBAUM, M.D. Cantab.,
F.R.C.P. Lond., &c.,
DIRECTOR OF THE CANCER RESEARCH IN UNIVERSITY COLLEGE AND THE
ROYAL INFIRMARY, LIVERPOOL; ASSISTANT PHYSICIAN TO THE
LIVERPOOL HOSPITAL FOR CONSUMPTION AND DISEASES
OF THE CHEST; ASSISTANT LECTURER AT THE LIVER-
POOL SCHOOL OF TROPICAL MEDICINE, ETC.

LECTURE I.[1]

Delivered on March 17th.

Mr. President and Gentlemen,—The first impulse—the natural impulse—of the Goulstonian lecturer for any year is to inquire what is known about his benefactor, what he did and what he accomplished. Meagre as are the materials for answering these questions there is one act of Dr. Goulston which will always be imprinted on the mind of his lecturer—I mean the expression of his desire that the lecturer should be chosen from among the four youngest Doctors of the Royal College of Physicians of London. The pleasurable sensation of an honour received, although unmerited—the ambition and failure to reach an ideal—even your youngest Doctor is already old enough to realise how much these sensations are inversely proportionate to age. For the opportunity of experiencing at once this feeling of pleasure, together with the sense of responsibility and want of success, I owe my obligations and thanks both to the memory of Dr. Goulston and Mrs. Goulston, and also to you, Sir, with the Fellows of this College.

In two more years three centuries will have passed since Francis Bacon, a contemporary of Dr. Goulston, published the "Advancement of Learning." His remarks on the state and progress of medicine in the seventeenth century were far from complimentary, yet we cannot deny their truth. But as some of his reproaches and advice guide the tenour of my lecture, expressing in finer and more pleasing language than I can imitate the goal which we in the twentieth century are still trying to reach, I trust you will forgive my quoting freely from his words. He says: "Medicine is a science which hath been more professed than laboured and yet more laboured than advanced, the labour having been in my judgement rather in circle than in progression. …… In the inquiry which is made by anatomy, I find much deficience: for they enquire of the parts and their substances, figures, and collocations; but they enquire not of the diversities of the parts …… of the secrecies of the passages and the seat or nestling of the humours, nor much of the footsteps and impressions of diseases. …… And for the humours, they are commonly passed over in anatomies as purgaments, whereas it is most necessary to observe what cavities, nests, and receptacles the humours do find in the parts, with the differing kind of the humour so lodged and received. And as for the footsteps of diseases …… they ought to have been exactly observed by a multitude of anatomies and the contribution of men's several experiences. …… I will not doubt to note as a deficience that they enquire not the perfect cures of many diseases, or extremities of diseases, but pronouncing them incurable do enact a law of neglect and exempt ignorance from discredit."

It is "the humours, the footsteps of disease and perfect cures" and their relations to one another which I shall attempt to describe, for within this triangle lie the theories of immunity and their clinical application. A little further on Bacon says: "They be the best physicians which being learned incline to the traditions of experience, or being empirics incline to the methods of learning." Fifty years later Sydenham, the English Hippocrates, was following these precepts and since he first struck out on the path of healthy empiricism English medicine has never left it. There can be no doubt that bedside and laboratory medicine must go hand in hand; at one time the eye or ear, at another the microscope or test-tube, may first descry the new disease—its manifestations or its cause. The correlation between bacterial cause and clinical symptoms is not always very evident and some sceptical spirits are disposed entirely to deny such relation. On the other hand, there are also some minds who fulfil Cicero's dictum concerning the unscientific thinking of the physician of his time: "Medici causa morbi inventa curationem inventam putant," substituting for "medici" the word "bacteriologici." It is not unreasonable to hope that some day finding the cause will mean also finding the cure, but that goal is not yet within sight. By good fortune it has occasionally been possible in the past to find a cure whilst we were yet ignorant of the cause and I trust that this may be so for still some time to come. But it is certain that without a knowledge of the cause we cannot explain or intelligently anticipate the symptoms of disease and the treatment can only be empirical; successful empiricism based on long and accurate experience it may be, satisfying perhaps to the patient and to mankind in general, but to the thoughtful physician unsatisfactory to a degree. He has also the disconcerting knowledge, based on his experience, that some day, unexpectedly, this empirical treatment will fail him. There is, then, every reason for trying to make disease and remedy premisses of the same syllogism the conclusion of which is health. The modern theories of immunity—and in particular that of Paul Ehrlich—based as they are upon ingenious and imaginative experiment have brought us appreciably nearer to a rational etiology and rational therapeutics of infective disease. I hope to show you that they have done even more than this and will do yet more. As on the Indian juggler's ladder, the topmost rungs are out of sight—heavenwards.

It would be unfair and ungracious to pass over entirely in silence the work of those far-sighted men, both clinicians and scientists, of the past and the present generations who in their mind's eye saw and expressed in prophetic language some of the achievements of to-day. Their thoughts will form convenient steps for us to follow.

At the latter end of the eighteenth century Hufeland, the celebrated physician of Berlin, published his "Ideas on the Pathogenesis and Influence of Vital Force on the Origin and Form of Diseases." Speaking of "contagium vivum …… an animal material, a special product of pathological-animal chemistry," he observes, amongst other more or less vague and erroneous statements, that "the contagious or infecting power of disease is relative, both as regards origin and effect. In origin because it depends on the degree of putrefaction and constitution of the subject suffering from the disease. As regards effect on other conditions, for here it depends on the susceptibility of the other for the reception of the contagium. Therefore the same disease may under certain circumstances and in certain subjects become contagious (e.g., consumption, of which it is known that in Italy it is reckoned among the infectious diseases; with us it is much less so) while under other circumstances and in other subjects it is not so, so that a disease may act contagiously on one man and not on another."

Half a century later these vague ideas, illuminated by subsequent observations, were brought to a focus by the logical mind of Henle. He showed by methods of argument and experiment akin to that of modern bacteriological investigation that scabies must be due to, and its transmission effected by, the *Acarus scabiei*. "Scabies cannot be transmitted by means of the matter from itch pustules, nor by freshly killed and pressed itch insects; it cannot be transmitted by the male but only by the impregnated female; the male causes a few local blisters, but scabies becomes a general and chronic skin disease only by the propagation of the insect on the infected body. …… The disease produced by a parasite which is communicated by accidental or intentional transplantation of the parasite is on that account infectious or contagious; the specific parasite is the infectious material or contagium of these diseases." Henle fought against the prevailing hazy and mystical conceptions of contagion, prophetically remarking: "I am firmly convinced that this is the way to condemn the doctrine to eternal darkness"; and, indeed, not until this path was abandoned did the doctrine again emerge from obscurity and itself become a source of light. Henle went even further and discussed the bearing of disposition of the host and the possibility of the production of a poison being

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Office, 423 Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed

THE LANCET can be obtained at all Messrs. W H. Smith and Son s and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J ASTIER, 8, Rue Traversière, Asnières, Paris.

vertebrates, especially warm blooded vertebrates, there are two kinds, which Metchnikoff designates as macrophages and microphages respectively They correspond to what the ordinary nomenclature calls large mononuclear leucocytes and the smaller polymorphonuclear white cells. On the introduction of any foreign matter, whether bacteria, metallic granules, or even sterile fluids, into the organism, the leucocytes leave their normal habitat, and, passing through the vessel walls, go to the attack, and often to the annihilation, of the intruder. Having surrounded and engulfed it, where possible, they then proceed to digest it. But when the foreign body is organised, the particular kind of leucocyte to lead the attack will vary according to the nature of that body The macrophages, as befits their larger, slower, and more unwieldy character have, according to Metchnikoff, a preference for animal cells—e.g , xanthocytes , for the bacteria of chronic disease—e g , tubercle and leprosy , and for the malarial and other analogous parasites The microphages, on the other hand, show a preference for the micro-organisms causing acute disease The phagocytic theory was in this crude condition in 1888 when Nuttall discovered the bactericidal action of serum and it received further blows by Behring's discovery of antitoxins in 1891 and Pfeiffer's finding of the bacteriolysins in 1894 But Metchnikoff has managed with considerable ingenuity to adapt his theory to these new factors and with much facility to abandon the purely mechanical explanation at first afforded by his theory

But since the modifications of Metchnikoff's theory and many of the experiments performed to support them are due to the evolution and development of Ehrlich's theory it will be well to consider the two theories side by side, or, rather to see what explanation is afforded by Metchnikoff's theory of Ehrlich's facts

Ehrlich's theory is really an outcome of his investigations into the nature of toxins and antitoxins He had early shown that as regards immunity similar results might be obtained with vegetable poisons to those obtained with bacterial toxins, also that the immunity obtained was to a large extent specific. In his experiments in 1891 on feeding and injecting animals with ricin he obtained from them a serum which protected other animals from a lethal dose and the immunised animals showed no reaction on solid ricin being applied to the conjunctiva. Yet on instilling a dilute (1 in 10,000) solution of abrin violent inflammation resulted, showing that the immunity existed for ricin only, or at any rate, had not been produced against abrin. By performing his experiments in a test tube outside instead of inside the body Ehrlich was able to show that the reaction is chemical and follows chemical laws He showed that for the agglomerating action of ricin on xanthocytes[2] vitality in the corpuscles was not essential, that the action could be inhibited by the addition of serum from a ricin immune animal, and that the relative proportion of ricin and serum required to form such a neutral mixture remained constant.

But the real starting point of Ehrlich's side-chain theory was his laborious investigation for the standardisation of diphtheria toxin Certain anomalous results occurred. The standardisation of the various samples of toxins was done with a standard serum. To a quantity of this serum able to neutralise 100 lethal doses were added successive quantities of toxin until two limits were obtained—one in which so much toxin was added that the antitoxin was just neutralised and the other in which there was just so much excess of toxin as to produce death in the test animal in four days Ehrlich found, firstly, that of various toxins a quantity less than 100 lethal doses often neutralised the standard quantity of antitoxin and, secondly, that the excess of toxin required to be added to the neutral mixture was more than one lethal dose. In order to explain this anomalous phenomenon Ehrlich assumed and finally proved the existence of a modification of the toxin, the "toxoid " which is nearly non poisonous but is nevertheless capable of uniting chemically with the antitoxin. The toxoids may again be subdivided into three groups according to their affinity for the antitoxin which may obviously be either greater (protoxoid), equal (syntoxoid) or less than (epitoxoid) that of the toxin When the affinity is less than that of the toxin to the antitoxin it is obvious that the epitoxoid will first be set free in the mixture and until they are all set free no toxin will be free, so that the difference between a neutral antitoxin + toxin mixture (L_0) and one just killing (L_+) will be several lethal doses. Ehrlich makes the following chemical comparison —

$$\begin{array}{llll}
\text{100 (epitoxoid} & + \ \text{antitoxin)} & + & \text{100 (toxin + antitoxin)} \\
\text{100 NaCH}_3\text{ COOH} & & + & \text{100 NaCl.} \\
\text{Add 101 units :} & \text{101 epitoxoid} & + & \text{101 toxin} \\
 & \text{101 CH}_3\text{ COOH} & + & \text{101 HCl} \\
\text{We get 200 NaCl} + & \text{201 CH}_3\text{, COOH} & + & \text{1 HCl.} \\
\text{(toxin + antitoxin)} & \text{(epitoxoid)} & & \text{(toxin)}
\end{array}$$

—viz., the difference between L_0 and L_+ is enormously increased by the presence of the epitoxoid. The modification from toxin into toxoid may be brought about in various ways and is perhaps comparable to the allotropic change occurring in the case of phosphorus When a toxin is kept some alteration takes place and its toxic power diminishes , it may apparently occur also by the action of high frequency *currents on toxin solutions Since the toxoids are not only* capable of producing immunity, but are also very much less poisonous, there may be some hope for the clinical treatment of diphtheria and tetanus within the solenoid by the conversion of toxin into toxoid within the living body

Having shown that the union of toxin and antitoxin occurs in fixed ratios, more rapidly in concentrated solution and in the warm, &c., Ehrlich deduces the following conclusions "The capacity of the toxin to saturate the antidotes must depend upon a specific atomic group of the toxin molecule, which group must have a maximal specific relationship to a definite atomic group of the antitoxin molecule, the one fitting easily into the other as a key into a lock, in the same manner as Emil Fischer has explained the specific action of ferment " Various observations tend to verify this statement Thus tetano toxin affects primarily the cells of the central nervous system and Wassermann showed that by previously mixing the toxin with an emulsion of brain substance it was neutralised. The affinity was specific emulsions of other organs were devoid of action. It appears most reasonable to assume that such specific atomic groups or antitoxin pre exist in small numbers and that their saturation by the toxin affords a stimulus to the cell for their reproduction. As Ehrlich says 'In the course of a typical process of immunisation the cell becomes trained, so to speak, to produce the specific side-chains in large quantity In such processes of regeneration, not compensation, but hyper compensation is the rule, and with the enormous increases of the poison dose a point must be reached when there is such an excess of side-chains that the cell is surfeited and casts them off as useless ballast into the blood." If, on the one hand, the presence of such receptive side-chains is a necessary condition for the occurrence of the toxic process this circumstance also explains in the most simple way the production of the antidotes.[3]" The existence and formation of the toxoids he explains as follows ' One must assume in the toxin molecule two independent atomic groups. One of these is haptophore and brings about the union with the antitoxin or the antitoxic side chains of the cells. The other atomic group is toxophore—viz., is the cause of specific toxic action ' The toxophore group is unstable and easily decomposed , with its decomposition the toxin is converted into the toxoid. The union of the haptophore group with the cell side-chain enables the toxophore group to act on the cell through the bridge thus formed , when the side-chain is circulating in the blood and becomes attached to the toxin molecule there is no cell on which it can exert its toxic action it is neutralised. There is further evidence in support of this view It is possible to immunise with toxoids alone Since by hypothesis their haptophore group should be able to unite with the cell side-chain quite apart from and without the lost toxophore group, this result is quite in accordance with theory

Starting from this central point it has been possible to explain a number of biological phenomena by similar reasoning and similar experiments, which in their turn confirmed the correctness of the original theory Pfeiffer's phenomenon gave the stimulus for this series of investigations Already before Pfeiffer's observation the bactericidal power of normal serum and its property of dissolving xanthocytes of other species, together with the loss of this power on heating to 56° C , had been observed and recorded The increased bactericidal power of the serum of an animal immunised against cholera without any antitoxic power was also known Its bacteriolytic the essential property of micro-organisms, thus anticipating many so called modern ideas of infection.

[3] I use this word instead of the hybrid enormity "antibody"

Of the clinicians Bretonneau and his pupil Trousseau were among the first to recognise specificity in disease and to overthrow the teaching of their time For the schools of Brown and Broussais were then still dominant, schools which allowed only quantitative differences in diseases producing similar symptoms To them cholera, typhoid fever, and ordinary intestinal catarrh were merely different manifestations of the same disease Trousseau devotes two lectures to the "specific element in disease and contagion," interesting and fascinating reading like all Trousseau's work, even to-day Permit me to quote some of his anticipating words "There are two factors one is the morbific germ coming from without and the other the economy about to receive it, there is required a special aptitude of the organism to respond to the action of the stimulus When there is no such predisposition the morbific germ perishes"

But from this time onwards there was a parting of the ways until now when they are once more coming together The fault lies largely with the bacteriologists, especially in Germany for they, in spite of Virchow's warning, until recently refused to take predisposition and susceptibility properly into account. On the other hand, the physicians have not been entirely blameless Sir Thomas Watson has more to say on predisposition than on specificity in disease and even his fine instinct led him so far astray as to deny the infectivity of phthisis To-day ideas of immunity and infection are so bound up with one another that an explanation of one carries with it the reason for the other But this was not always so In bygone ages immunity was the prevalent idea and applied only to mineral and vegetable poisons In recent times it has been limited largely to immunity against bacterial (vegetable) infection. In the future it will include both these and also immunity to cellular animal infection. Nay, more, if pushed to the limits it would appear that immunity is merely a special instance of the evolutionary laws concerning adaptation to environment But this is an altruism not yet capable of proof and we must return to palpable experimental facts and their meaning

Immunity may perhaps be defined simply as the power to resist infection. Metchnikoff thinks it at present impossible to give a more precise definition of immunity to infectious disease than "the complex of phenomena by which an organism can resist the attack of the specific pathogenic microbes," and the resistance, we may add, to their products. So far as I know Ehrlich, perhaps wisely, refrains from any definition

The two chief theories of the present day are those promulgated and supported by Metchnikoff and Ehrlich respectively Originally opposed to one another, like the humoral and iatro-chemical theories of the Middle Ages, they are really only rays of light refracted at different angles from the same source of light and will ultimately be made to fuse into one brilliant cellulo-humoral theory of immunity Not that we can accuse the upholders of the modern humoral theory as we could their predecessors of a period of bacterial supremacy, of neglecting the fundamental ideas of cellular pathology, it is merely a question of distribution. While, on the one hand, Metchnikoff and his school believe that the white cells directly attack the invading bacteria Ehrlich and his followers have laid more stress on the constituents of the body fluids. But even they regard a bacterial toxin as poisonous only in the form of a chemical combination with a cell constituent If the cell does not possess this constituent the bacterial toxin is innocuous—the cell possesses a natural immunity On the other hand, these cell constituents coursing in the blood are the protective bodies and they have had their origin in the cells. As Behring tersely puts it, "that substance in the living body which, when situate in the cell, is a preliminary essential to the toxic process becomes a curative agent when it enters the blood stream." To take a very gross illustration Suppose a ball of cotton wool to have wrapped up in it some small lumps of sodium carbonate and immersed in an acid fluid. There will be an evolution of gas in the ball and it will be partly disintegrated. If the ball had previously secreted these lumps the chemical reaction would have gone on outside

There are only two theories which we need consider at all in detail, but before attempting an exposition of these theories it will, I think, be better to describe a few of the phenomena of immunity and then to proceed to the explanations put forward The spirited contest between the exponents and their partisans of these two rival theories has led to the most ingenious and interesting experiments of modern biological investigation.

Immunity may be either congenital or acquired. When congenital true infection for particular disease is impossible Into the explanation of this phenomenon we shall inquire later This form of immunity is always natural. Acquired immunity may be either active or passive. By active immunity we understand that acquired either by an attack of the disease, in which case it is natural, or by inoculation, when it is artificial. In both instances a process of what may fairly be termed infection occurs. Passive immunity is produced by the introduction into one organism of the products of active immunity in another By the injection of the products of active immunity against diphtheria from the horse into the human subject the latter becomes passively immunised against the disease. But infection itself is not of a single kind and immunity will vary with the nature of the infection. The action of some infective agents—e.g, the tubercle bacillus and the leprosy bacillus—is largely mechanical, they produce fibroid and degenerative changes in the tissues which they attack. Others when introduced into the body do not multiply extensively but remaining at the site of inoculation perform their malignant functions by secreting poisonous substances to enter the circulation. To this group belong diphtheria and tetanus. Yet others are capable of multiplying in the tissue as well as producing poisons and so exert their influence in both ways

A suitable soil is essential for many bacteria. Introduced beneath the skin the comma bacillus is comparatively soon destroyed, but if put into the alimentary canal it produces cholera. Cutaneous infection with bacillus anthracis produces severe illness, but taken into the alimentary canal it is practically harmless The tubercle bacillus by whatever route it may enter the body can settle, multiply, and produce its specific lesions It must be remembered that the mere presence of a specific bacillus is not evidence either of infection or immunity of the organism in which it is found, for the tubercle bacillus has been found in the sputum the typhoid bacillus in the fæces, and the diphtheria bacillus in the throat of healthy persons Both are relative terms, there is no certain infection or absolute immunity Infection, then, may be due chiefly either to the micro-organism or its products. Corresponding to these two modes we can distinguish two classes of immunity—viz, a bactericidal and an antitoxic immunity Again corresponding to these distinctions we find a variable duration of immunity, it may be only for months or it may be for years It may be slight or nearly absolute, and finally it may be either individual or racial.

Let us now consider the two chief theories put forward to explain the phenomena of immunity, and taking them in their historical order commence with that of Elias Metchnikoff.

Metchnikoff was originally a zoologist who, as he himself tells us has "strayed into the domain of chemical biology and of medical science," and his theory is essentially that of a zoologist. I should like to make it clear that I say this in no depreciatory sense. On the contrary, nobody, I hope, can be more alive to the interdependence of the several sciences and particularly of the dependence of the science of medicine—I say advisedly the science, not the art, of medicine—on the sister sciences. It is rather with the object of directing attention to the way in which a theory based on the broad principles of cellular biology has been applied to the special problems of disease as contrasted with another theory which, starting from the comparatively narrow basis of disease, is finally found applicable and pertinent to many wide biological problems The starting point of Metchnikoff's theory was the observation that the protozoa habitually ingest and digest bacteria, whether pathogenic or no—that the bacteria form for them an important aliment. On the other hand, the more highly developed organisms with a digestive tract are unable to digest bacteria, but when they enter the circulation, unless they are pathogenic, they disappear, and not by way of the kidneys unless the latter are injured Passing up the line of increasing complexity of organisation we find these large cells at first distributed in the alimentary canal or along the external surface of the organism, until finally they are confined to the blood stream. The blood of the invertebrates contains but a single kind of amœboid cell, in the vertebrates, especially warm blooded vertebrates, there are two kinds, which Metchnikoff designates as macrophages and microphages respectively They correspond to what the ordinary nomenclature calls large mononuclear leucocytes and the smaller polymorphonuclear white cells. On the introduction of any foreign matter, whether bacteria, metallic granules, or even sterile fluids, into the organism, the leucocytes leave their normal habitat, and, passing through the vessel walls, go to the attack, and often to the annihilation, of the intruder Having surrounded and engulfed it, where possible, they then proceed to digest it. But when the foreign body is organised, the particular kind of leucocyte to lead the attack will vary according to the nature of that body The macrophages, as befits their larger, slower, and more unwieldy character have, according to Metchnikoff, a preference for animal cells—e.g , xanthocytes , for the bacteria of chronic disease—e g , tubercle and leprosy , and for the malarial and other analogous parasites The microphages, on the other hand, show a preference for the micro-organisms causing acute disease The phagocytic theory was in this crude condition in 1888 when Nuttall discovered the bactericidal action of serum and it received further blows by Behring s discovery of antitoxins in 1891 and Pfeiffer's finding of the bacteriolysins in 1894 But Metchnikoff has managed with considerable ingenuity to adapt his theory to these new factors and with much facility to abandon the purely mechanical explanation at first afforded by his theory

But since the modifications of Metchnikoff's theory and many of the experiments performed to support them are due to the evolution and development of Ehrlich's theory it will be well to consider the two theories side by side, or, rather to see what explanation is afforded by Metchnikoff s theory of Ehrlich's facts

Ehrlich s theory is really an outcome of his investigations into the nature of toxins and antitoxins He had early shown that as regards immunity similar results might be obtained with vegetable poisons to those obtained with bacterial toxins, also that the immunity obtained was to a large extent specific. In his experiments in 1891 on feeding and injecting animals with ricin he obtained from them a serum which protected other animals from a lethal dose and the immunised animals showed no reaction on solid ricin being applied to the conjunctiva. Yet on instilling a dilute (1 in 10,000) solution of abrin violent inflammation resulted, showing that the immunity existed for ricin only, or, at any rate, had not been produced against abrin By performing his experiments in a test tube outside instead of inside the body Ehrlich was able to show that the reaction is chemical and follows chemical laws He showed that for the agglomerating action of ricin on xanthocytes[2] vitality in the corpuscles was not essential, that the action could be inhibited by the addition of serum from a ricin immune animal, and that the relative proportion of ricin and serum required to form such a neutral mixture remained constant.

But the real starting point of Ehrlich's side-chain theory was his laborious investigation for the standardisation of diphtheria toxin Certain anomalous results occurred. The standardisation of the various samples of toxins was done with a standard serum. To a quantity of this serum able to neutralise 100 lethal doses were added successive quantities of toxin until two limits were obtained—one in which so much toxin was added that the antitoxin was just neutralised and the other in which there was just so much excess of toxin as to produce death in the test animal in four days Ehrlich found, firstly, that *of various toxins* a *quantity* less than 100 lethal doses *often* neutralised the standard quantity of antitoxin and, secondly, that the excess of toxin required to be added to the neutral mixture was more than one lethal dose. In order to explain this anomalous phenomenon Ehrlich assumed and finally proved the existence of a modification of the toxin, the "toxoid" which is nearly non-poisonous but is nevertheless capable of uniting chemically with the antitoxin. The toxoids may again be subdivided into three groups according to their affinity for the antitoxin, which may obviously be either greater (protoxoid), equal (syntoxoid), or less than (epitoxoid) that of the toxin. When the affinity is less than that of the toxin to the antitoxin it is obvious that the epitoxoid will first be set free in the mixture and until they are all set free no toxin will be free, so that the difference between a neutral antitoxin + toxin mixture (L_0) and one just killing (L_+) will be several lethal doses. Ehrlich makes the following chemical comparison —

$$\begin{array}{llcl}
\text{100 (epitoxoid} \quad + & \text{antitoxin)} & + & \text{100 (toxin + antitoxin)} \\
\text{100 } NaCH_2\,COOH & & + & \text{100 } NaCl \\
\text{Add 101 units} \quad : & \text{101 epitoxoid} & + & \text{101 toxin,} \\
 & \text{101 } CH_3\,COOH & + & \text{101 } HCl\,; \\
\text{We get 200 } NaCl \quad + & \text{201 } CH_3\,COOH & + & \text{1 } HCl \\
\text{(toxin + antitoxin)} & \text{(epitoxoid)} & & \text{(toxin)}
\end{array}$$

—viz., the difference between L_0 and L_+ is enormously increased by the presence of the epitoxoid. The modification from toxin into toxoid may be brought about in various ways and is perhaps comparable to the allotropic change occurring in the case of phosphorus When a toxin is kept some alteration takes place and its toxic power diminishes , it may apparently occur also by the action of high frequency currents on toxin solutions Since the toxoids are not only capable of producing immunity, but are also very much less poisonous, there may be some hope for the clinical treatment of diphtheria and tetanus within the solenoid by the conversion of toxin into toxoid within the living body

Having shown that the union of toxin and antitoxin occurs in fixed ratios, more rapidly in concentrated solution and in the warm &c., Ehrlich deduces the following conclusions "The capacity of the *toxin to* saturate the antidotes must depend upon a specific atomic group of the toxin molecule, which group must have a maximal specific relationship to a definite atomic group of the antitoxin molecule, the one fitting easily into the other as a key into a lock, in the same manner as Emil Fischer has explained the specific action of ferment." Various observations tend to verify this statement Thus tetano toxin affects primarily the cells of the central nervous system and Wassermann showed that by previously mixing the toxin with an emulsion of brain substance it was neutralised. The affinity was specific emulsions of other organs were devoid of action. It appears most reasonable to assume that such specific atomic groups of antitoxin pre exist in small numbers and that their saturation by the toxin affords a stimulus to the cell for their reproduction. As Ehrlich says "In the course of a typical process of immunisation the cell becomes trained *so to speak*, to produce the specific side-chains in large quantity In such processes of regeneration, not compensation, but hyper compensation is the rule, and with the enormous increases of the poison dose a point must be reached when there is such an excess of side-chains that the cell is surfeited and casts them off as useless ballast into the blood." 'If, on the one hand, the presence of such receptive side-chains is a necessary condition for the occurrence of the toxic process this circumstance also explains in the most simple way the production of the antidotes.[3]" The existence and formation of the toxoids he explains as follows ' One must assume in the toxin molecule two independent atomic groups One of these is haptophore and brings about the union with the antitoxin or the antitoxic side chains of the cells. The other atomic group is toxophore—viz , is the cause of specific toxic action " The toxophore group is unstable and easily decomposed , with its decomposition the toxin is converted into the toxoid. The union of the haptophore group with the cell side-chain enables the toxophore group to act on the cell through the bridge thus *formed* , when the side-chain is circulating in the blood and becomes attached to the toxin molecule there is no cell on which it can exert its toxic action it is neutralised There is further evidence in support of this view It is possible to immunise with toxoids alone Since by hypothesis their haptophore group should be able to unite with the cell side-chain quite apart from and without the lost toxophore group, this result is quite in accordance with theory

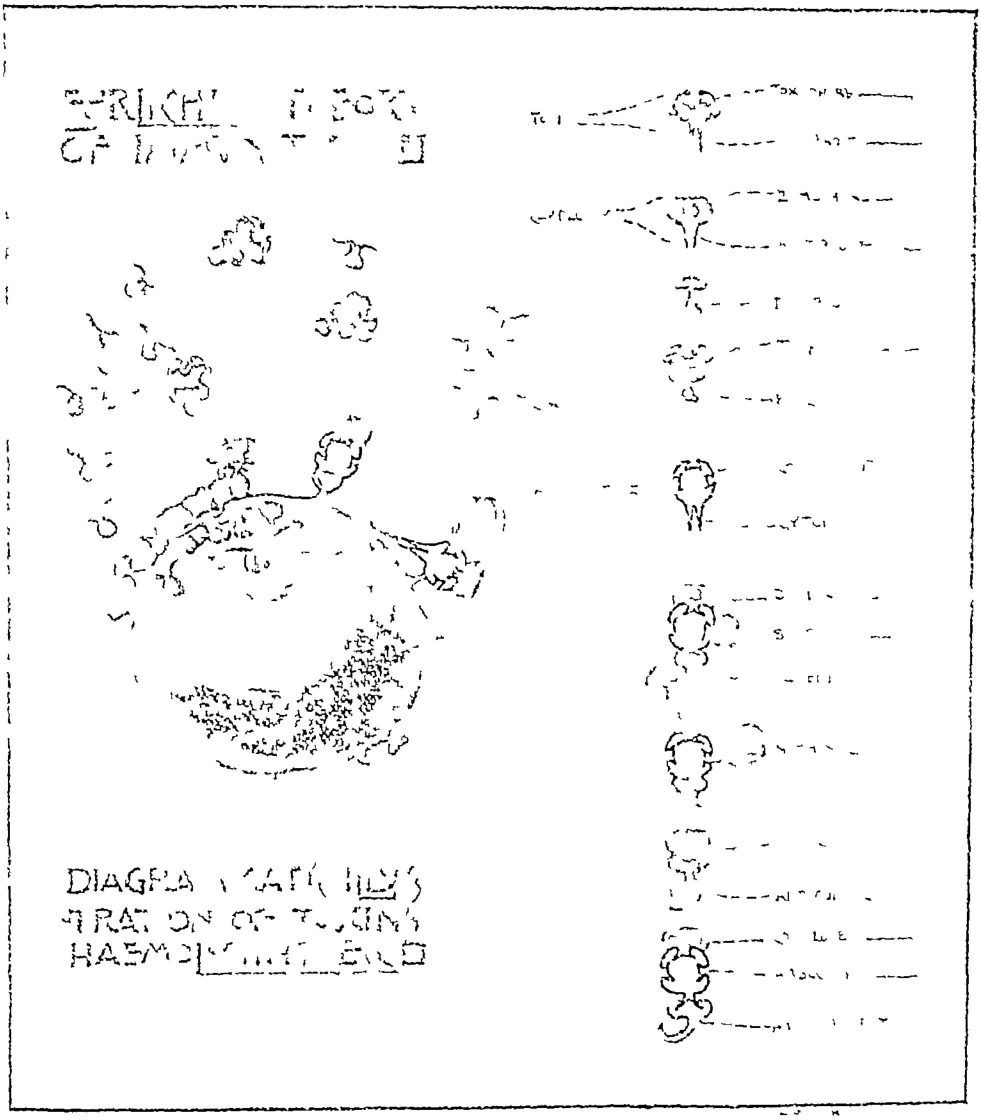
Starting from this central point it has been possible to explain a number of biological phenomena by similar reasoning and similar experiments, which in their turn confirmed the correctness of the original theory Pfeiffer s phenomenon gave the stimulus for this series of investigations Already before Pfeiffer s observation the bactericidal power of normal serum and its property of dissolving xanthocytes of other species together with the loss of this power on heating to 56° C , had been observed and recorded The increased bactericidal power of the serum of an animal immunised against cholera without any antitoxic power was also known Its bacteriolytic property was yet unknown Pfeiffer found that either by the simultaneous intraperitoneal injection of a lethal dose of cholera vibrios, together with the serum of an immunised animal, or by the injection of the cholera vibrios alone into the abdominal cavity of an immunised animal, the micro organisms lost their motility, became spherical, and then underwent a granular degeneration, while the animal survived (Pfeiffer's phenomenon) It was shown by Fränkel and Sobernheim that this result obtained also if the immune serum had been previously heated to 56° C and its bactericidal power consequently destroyed. It follows that if the bactericidal substance plays any part in this reaction it must be supplied from the blood of the animal subjected to the experiment. Bordet proved that two substances contributed to Pfeiffer's reaction by showing, firstly, that it occurred *in vitro* and, secondly, that if the bactericidal property of the immune serum were destroyed by first heating it to 56° C the bacteriolytic action could be restored by the addition of a small quantity of normal serum.[4] By similar experiments, using xanthocytes instead of bacteria for immunisation, Bordet was able to show that the hæmolytic power of the immune serum was destroyed by heating and could be restored by the addition of normal serum which by itself possessed no hæmolytic properties

---

[2] Vide Sherrington Brit Med Jour 1901, p 742

[3] I use this word instead of the hybrid enormity antibody"

In order to extend his theory of the formation of antitoxins to that of hæmolysins Ehrlich made a long series of experiments. He recognised, of course, that Bordet was right in assuming the existence of two bodies for the production of the phenomenon and that one body (mediator amboceptor) was present in quantity in the serum of immunised animals only, while the other (the complement) occurred in the serum of normal untreated animals. He reasoned that if the hæmolysin were formed in a similar way to antitoxin, then it ought to be saturated and neutralised by the addition of xanthocytes which would correspond to the toxin in an antitoxin mixture. This was proved to be so by taking the serum of a goat immunised against sheep's blood, heating the serum to 56° C to destroy its hæmolytic power (by the destruction of the complement), and then adding to it sheep's xanthocytes. After standing awhile they were again separated by centrifugalising If the mediator had united with xanthocytes then on the addition of normal serum to the corpuscles hæmolysis ought to occur This was found to be the case. On the other hand, if the mediator had been removed from the immune serum, then on the addition of fresh normal serum and xanthocytes to it no hæmolysis of the latter should occur Nor did it This proved, as Ehrlich says, "that the amboceptor possesses a specific haptophore group which binds it to the xanthocyte, as required by the side-chain theory" On the other hand, if to normal goat's serum, which contains the second body, the complement, there be added sheep's



---

[4] It will be convenient to note here that a serum deprived of such a property by heating is called an inactivated serum and when this property is restored a reactivated serum

xanthocytes, then, if they were capable of binding the complement, on centrifugalising off the xanthocytes and adding fresh xanthocytes and mediators to the removed supernatant serum, no hæmolysis should occur. But it does, showing that the complement has not united with the xanthocytes. Moreover, if xanthocytes and immune serum be mixed as before, but kept in the cold, no hæmolysis occurs. On centrifugalising and treating the xanthocytes as just mentioned one can prove that the amboceptor has united with the xanthocyte, but not the complement with the intermediary body. Since the interposition of the amboceptor is thus shown to be essential Ehrlich concludes "that the amboceptor has two different haptophore groups, one having a great affinity to the corresponding haptophore group in the xanthocyte and a second haptophore group of less chemical energy which can attract more or less completely the complement present in the serum."

Since the action of the complement produces effects which with Pfeiffer we must regard as analogous to digestion, we shall probably not be far wrong in regarding the complement as possessed of the properties of a digestive ferment. Taking a familiar illustration—in which, however, the characters are really reversed—we may regard the pepsin in an artificial digestion mixture as the amboceptor and the acid as the complement. That is, the pepsin is the special factor, like the amboceptor occurring only in the immune serum, while the acid which may, as we know, be either hydrochloric, or sulphuric, or oxalic, &c., corresponds to the complement to be found in a variety of sera. The lock and key simile of E. Fischer affords perhaps the best analogy. The lock is the cell, the key is the amboceptor, and the hand which turns the key is the complement. As a rule but one key (or at most a few similar ones, a small number compared with all) will fit a given lock. But nearly any hand, it may be of a monkey or performing dog, can turn the key in the lock. The same explanations hold good for the action of the agglutinins—viz., those substances in immune sera which cause agglutination of the corresponding bacteria, and for the action of the precipitins—viz., those substances in immune sera which cause precipitation when added to the fluids or solutions of substances used for immunisation. In the case of milk they have been called coagulins.

I shall return later to these particular substances. It will suffice here to point out that their occurrence led Ehrlich to expand his hypothesis and to apply it to explain also the normal processes of food assimilation. The formation of antibodies to normal food stuffs is quite analogous to the formation of antitoxins to toxins, so that the generation of antitoxins "is only a reproduction of a process in normal cell life." Ehrlich believes that the proteid molecule of a food becomes attached to one group of the cell receptor while the other group is already occupied by a ferment (the complement) molecule to make the food stuff assimilable. In this respect the receptor is more complicated than that for the toxin which has only one group, but is less complicated than that concerned with the formation of hæmolysins, cytolysins, &c. In the last instance separate groups are required for union with the broken down bacteria or xanthocytes and for the complement circulating in the blood stream. This can be most easily explained by reference to the diagrams (modified from Ehrlich) and to the models.

ROYAL NATIONAL PENSION FUND FOR NURSES.—The annual meeting of the members of this society, of which Her Majesty the Queen is the President, was held on March 12th at River Plate House, Finsbury circus, E.C. Sir Henry Burdett, K.C.B., the deputy chairman, presided in the absence of the chairman, who is abroad, and moved the adoption of the report for 1902. In the pension branch the number of policies issued was 869 as against 842 in 1901. Progress is shown in the work of the annuity branch. At the end of 1901 there were 339 annuitants holding 500 policies, while on Dec. 31st, 1902, there were 415 annuitants under 598 policies and for the December quarter annuities were being paid out at the rate of over £8000 a year. The amount distributed in sick pay was £1568, as against £1633 in 1901. The percentage of expenses to premium income—3·26 per cent.—was lower than it had been in any previous year and considerably below the average for the past five years which is 3·56 per cent. The total

ABSTRACT OF

The Hunterian Lectures

ON

SOME POINTS IN THE ANATOMY AND PATHOLOGY OF THE VERMIFORM APPENDIX.

Delivered before the Royal College of Surgeons of England on March 9th, 11th, and 13th, 1903,

BY W. McADAM ECCLES, M.S. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; LATE SENIOR ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL; ASSISTANT SURGEON TO THE CITY OF LONDON TRUSS SOCIETY, ETC.

LECTURE III.[1]

Delivered on March 13th.

MR. PRESIDENT AND GENTLEMEN,—Recently the association of appendicitis with joint lesions has been brought before the notice of the profession by several observers and arthritis as a complication or sequela of appendicitis is worthy of further investigation.

THE ASSOCIATION OF APPENDICITIS WITH JOINT LESIONS.

Any infective process in the body may be associated with secondary affections of the synovial cavities. The arthritis of gonorrhœa and that of scarlet fever are two only of many instances which may be cited in this connexion. It is therefore self evident that in the infective processes occurring in the appendix there will be a liability for a similar condition to supervene. Whether, however, this should be spoken of as a rheumatic affection is quite another matter. I have previously stated that I believe all cases of distinct appendicitis are dependent upon the action of micro-organisms. If ordinary articular rheumatism associated with cardiac lesions in many instances is in reality due to the invasion of a specific diplococcus, then there is no doubt but that it is possible for this organism to infect the lymphoid tissue of the appendix in much the same way that it does the adenoid tissue of the palatine tonsils. I am unaware, however, of any case in which an excised appendix has been shown to be infected with this coccus, so recently described by Dr. F. J. Poynton and Dr. A. Paine.[2]

Personally in the somewhat rare cases in which definite joint lesions are associated with inflammation of the appendix, I look upon the arthritis as wholly secondary to the appendicitis, of the nature, perhaps, of a subacute pyæmia, rather than that both joint affection and appendix inflammation are coincidently due to the same general infection. It is true that the colon bacillus may induce an arthritis which has many of the characteristics of that of ordinary rheumatism, but it is more common in such cases to find that the fluid formed within the joints is sero-fibrinous, semi purulent, or even well marked pus. A practical outcome of this view of the condition is that if there be a source of infection in the appendix the sooner this is removed the safer for the patient.

INFLAMMATION OF THE APPENDIX ASSOCIATED WITH PREGNANCY AND PARTURITION.

The association of appendicitis with pregnancy and parturition is one of the gravest import and one which is by no means uncommon. That a woman who has suffered from an attack of appendicitis and has not had the organ excised runs an enormous risk if she becomes pregnant is now coming to be a well recognised fact. It is difficult to judge whether the occurrence of the pregnancy is a factor in the lighting up of the inflammation in the appendix, but it is equally certain that such an inflammatory condition commencing during pregnancy or after parturition has up to now been attended with often fatal results. This unhappy termination, I think, in many cases is due to a want of early recognition of the lesion and of its prompt surgical treatment.

---

[1] Lectures I. and II. were published in THE LANCET of March 14th, 1903, p. 703.

[2] Transactions of the Pathological Society of London, 1901, p. 10

Appendicitis occurring during pregnancy—Inflammation of the appendix may supervene at any period of pregnancy Appendicitis is graver in its prognosis the longer pregnancy has been in existence It will lead frequently to the death of the fœtus or of the mother and fœtus In the early months of pregnancy there is often some disturbance of the digestive system and constipation is not uncommon, for constipation is very frequent among women and pregnancy aggravates it. It may be that these troubles have a bearing on the incidence of appendicitis The history of a previous attack of inflammation of the tube is always of great importance in arriving at a correct diagnosis, but a primary attack may show itself in a pregnancy There can be little doubt that if signs and symptoms of appendicitis show themselves in the first three months of pregnancy the safest course is to treat the case as if it were one in which no fœtus resided within the uterus—that is, to deal with it surgically At this early stage of pregnancy abortion is not a serious complication of an operation upon an appendix, but to delay surgical interference in the appendicitis of early gestation because of the possibility, or even probability, of abortion is to subject the patient to a very real and very serious risk. When, however, inflammation of the appendix does not show itself until after the uterus has risen out of the pelvis, and especially in those instances in which the appendix lies over the brim of the pelvis, a much more complicated condition necessarily ensues. It is then that the uterus approaches the dangerous region near the appendix and renders it likely that its own serous covering may in part form the wall of an abscess cavity connected with the diseased organ From this will easily be seen the extreme danger of the condition.

As to the diagnosis of appendicitis in pregnancy from the fourth month onwards the difficulties are distinctly increased. The presence of the enlarged uterus, the want of softness of the abdominal walls, and the symptoms, such as vomiting and constipation referable to the pregnant state, are all obstacles to a conclusive decision as to the exact site of the inflammatory mischief Here, again, the history of a previous attack is of the greatest assistance. I am chiefly inclined to rely upon the sudden onset of the symptoms, the marked rigidity of the right rectus, and the early localisation of the pain in the right iliac fossa. A rapid rise of temperature with a quickened pulse rate, vomiting, the discovery of nothing definite by a careful vaginal and rectal examination, and the presence of leucocytosis are all aids to a correct diagnosis. But it is safer in a really doubtful case to assume that inflammation of the appendix is present than to temporise and to delay an exploration until too late The all important question is the one of treatment after a diagnosis has been arrived at

Miscarriage or premature labour is almost certain to occur and with it arises the chief danger of the condition both with regard to the mother and the child. Seeing that this complication is almost inevitable the treatment must be directed so as to minimise the danger attending it. As in appendicitis occurring in the male or the non pregnant female the line of action may be non operative or operative From the record of published cases, and probably still more from those that remain unpublished, the results in those instances in which the inflammatory condition has been allowed to progress to perforation or gangrene of the appendix and to suppuration around it have in at least 70 per cent been disastrous, both mother and child dying It would therefore seem to be rational and wisest to operate upon all cases of even suspected appendicitis in pregnancy at the earliest possible moment, disregarding the fact of the gravid uterus and dealing with the appendix. If the uterus does empty itself it will do so with much less danger if there is no abscess cavity in proximity to it and although the life of the child will probably be sacrificed that of the mother may be saved Further, supposing the uterus retains its contents there is good hope for both mother and child Seeing that the termination of expectant treatment, even supposing the pus finds its way into the bowel, is so uncertain and so fatal, it can hardly be worse from prompt surgical interference and might be a good deal better

With regard to the suggestion that the uterus should be made to discharge its contents by artificial interference before an operation on the inflamed appendix is undertaken, I cannot see what benefit can accrue from such a proceeding If an operation is performed without the uterus being emptied previously, the child's life may be saved. If pus should have formed it is possible, and even probable, that the alteration in the position of the uterus, consequent upon its contraction, may tear down adhesions and flood the peritoneal cavity with the septic fluid. If, on the other hand, the abscess cavity is opened and even merely flushed out there will be less danger of general infection than if the uterus subsided with pus pent up under tension. There should be no need to have to empty the uterus artificially if the condition of the appendix is diagnosed and treated early

Appendicitis occurring during the puerperal state—Appendicitis manifesting itself after parturition is somewhat different in its course and in its termination to that occurring during gestation. It is possible for the condition to be in evidence, or latent, during the last few days of pregnancy, and for it to be fanned into activity by the disturbance caused by delivery A woman with a diseased appendix, as, for instance, when the organ contains a calculus and lies over the brim of the pelvis, is placed in distinct danger of an acute attack soon after the commencement of the puerperium The condition is then most apt to be mistaken for a septic condition dependent upon infection of the interior of the uterus, but there are several signs which should serve to distinguish the appendix inflammation from the uterine sepsis. The lochia remain sweet, vaginal examination may reveal nothing abnormal, pain localises itself to the right iliac fossa, intra uterine douching does not effect any lowering of the temperature, marked leucocytosis may be found and a history of previous attacks may be gleaned. The prognosis is not so grave as in the cases of appendicitis complicating pregnancy, but it is sufficiently serious to make the cases very anxious ones to the medical attendants and friends I consider that each case should be treated on the lines that would be considered best if the condition was not complicated by a recent delivery

APPENDICITIS IN RELATION TO LIFE INSURANCE.

There can be no doubt that as the medical examiner is becoming more and more inclined to look upon the history of pleurisy in a proposer as one very suspicious of tubercle, so he will be likely to regard the vague term of "inflammation of the bowels" or even the still more common "bilious attacks" as possibly indicative of recurrent appendicitis. It is extremely difficult to arrive at any degree of accuracy as to the death rate from appendicitis but that in the present day it really is the primary cause of a large number of deaths assigned to "peritonitis," "inflammation of the bowels," and other such lesions there can be but little doubt. Hernia is practically always inquired about in a proposal form but a question seeking information as to the occurrence or not of signs or symptoms of appendicitis is hardly if ever put, and yet I venture to think—and here, again it is difficult to prove—that the latter lesion produces a death rate far in excess of that of the former Then, again, it is important to remember that appendicitis is a disease affecting particularly young adults, and especially the male sex just the particular class of person most usually seeking to become insured Against loss by death from a primary attack of inflammation of the appendix it is probable that insurance offices cannot be protected, but as a precaution all examiners should pay careful attention to intestinal history which is at all suggestive of an attack even if this is very indefinite. I am sure in any suspicious proposal it is of great importance to weigh the habits of the proposer in respect of diet, hurried meals, and action of the bowels and also the condition of the teeth.

Given, on the other hand, a proposer in whom a fairly definite attack of inflammation of the appendix but without operative treatment has occurred, what is to be the attitude of the medical examiner in expressing his opinion as to the eligibility of the life? It is here that extremes meet. Some would refuse to accept unless the appendix has been removed, others would pass without loading provided that two years had elapsed since the attack. Personally I am inclined to load, say with seven to ten years extra most cases in which an attack of appendicitis has been diagnosed and the appendix remains *in situ*. It is well known that although a first attack which is recognised may be apparently a very slight one, yet the second may lead to the death of the sufferer On the other hand a case in which the appendix has been removed and the scar resulting is sound may be accepted at the ordinary rates six months after the laparotomy When there has been more than one attack I should not pass the proposer unless the appendix had been successfully removed.

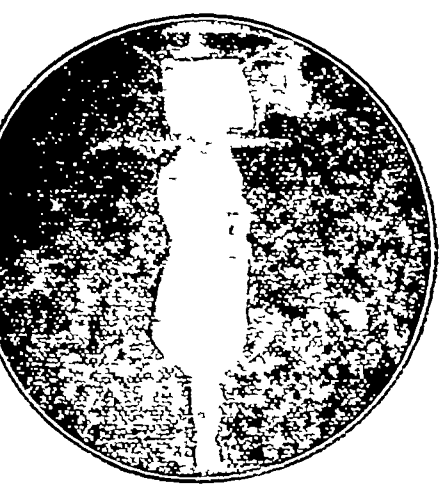
Then there are those cases in which an abscess has formed and has been drained without the removal of the appendix. If relapse was common in these conditions it would be again necessary to charge an extra premium, but second attacks are distinctly rare, some 3 to 4 per cent being probably about the proportion. Moreover, when a relapse does occur it usually takes place within the first year after the suppuration. Thus, other things being equal, the life may be accepted provided there have been no secondary signs for two years following the drainage.

NEW GROWTHS OF THE APPENDIX.

New growths of the appendix are rare. They may be innocent or malignant.

Innocent new growths are extremely rare. Examples have been recorded of lipomata, myomata, and lymphadenomata. I have been unable to find actual specimens of these conditions. Deaver[3] records two instances of fibro-myoma of the appendix. One was from a patient, the subject also of fibro-myomata of the uterus, and both organs were removed at the same operation. The appendix presented two fibroid growths, each of which was spheroidal in shape and about five millimetres in diameter. One was situated at the mid-point of the appendix opposite the attachment of the mesentery, and the other towards the tip of the organ within the mesenteric attachment. They projected somewhat from the surface of the appendix and each was well circumscribed, surrounded by a rather dense capsule, and was firm to the touch. On section they were whitish and glistening and revealed a fibrillar structure. One was much harder than the other—being of almost stony hardness—and cut with a grating sensation. The wall of the appendix elsewhere was much thickened and the lumen was much constricted. The mucous membrane appeared smooth and atrophic. On microscopical examination there were detected the lesions of moderate interstitial appendicitis, with considerable thickening of the walls of the blood-vessels. The tumours consisted of bundles of dense fibrous connective tissue that coursed in various directions and intertwined among themselves and interspersed between them was a small number of unstriped muscular fibres. The growth opposite the meso-appendix contained a considerable amount of calcareous infiltration. The second case was like the first. There is in the museum of St. Bartholomew's Hospital a specimen of a simple papilloma of the mucous membrane of the appendix. About one-third of the distance along the appendix from the cæcum there project from the mucous membrane lining the lumen three well marked papillomatous growths. The largest of these is about half an inch in length and hangs freely into the cavity of the appendix which is apparently somewhat dilated. The papillomata were innocent in nature and covered with typical columnar epithelium.

FIG. 9.



Papilloma of the vermiform appendix (St. Bartholomew's Hospital Museum).

Malignant new growths of the appendix are not so rare as are innocent growths, but they are sufficiently uncommon to make their occurrence a matter of interest and one for record. Such neoplasms are primary or secondary. New growths secondary to malignant disease primary elsewhere in the abdomen are not so very infrequent. Rolleston has remarked that it is possible that primary malignant new growths of the appendix are not so rare as is commonly supposed and he accounts for the scarcity of records from two causes, first, because the appendix may be removed for symptoms of appendicitis in quite the early stages of carcinoma and for want of a histological examination the presence of the new growth may be overlooked, and secondly, because if the disease is not removed early it will run its course, and at the post-mortem examination it will be difficult or impossible to say where the primary lesion originated. Both carcinoma and sarcoma are met with in the appendix, and also the growth which is now termed endothelioma. Carcinoma is found either of the columnar celled, adeno-carcinoma, or of the spheroidal celled variety. Such epithelial new growths have their origin in the epithelium of the glands or crypts in a manner similar to carcinoma of the large intestines.

There are two interesting points in the question of the etiology of carcinoma of the appendix. Do previous attacks of inflammation predispose to the commencement of the neoplasm? Does the presence of appendicular calculi tend to induce the cancerous condition? Unfortunately the records of instances of primary carcinoma of the appendix are not too comprehensive and therefore data are somewhat wanting which would lead to a satisfactory conclusion on these points. I have been able to collect only 14 instances of undoubted primary carcinoma and three of undoubted primary sarcoma or endothelioma. In only two out of these 17 is there any mention of an appendicular calculus being present. In five, on the other hand, there is a definite history of one or more previous attacks of appendicitis, in some of which a former attack had occurred several years before the one which led to the excision of the organ. While, therefore, there is scanty evidence of appendicular calculi being a predisposing cause of carcinoma in a manner similar to that in which biliary calculi are thought to be precursors of cancer of the gall bladder there is more in favour of previous attacks of appendicitis being related to the incidence of carcinoma.

HERNIA OF THE VERMIFORM APPENDIX.

The number of instances in which the vermiform appendix has been found in hernial sacs is becoming more numerous every day, not probably because the actual cases are more numerous but because there are many more operations for hernia at the present time than formerly. The appendix may constitute the sole contents of a hernial sac or it may be present with other viscera. The latter condition is chiefly concerned with cæcal hernia and will not therefore be discussed.

The appendix as the sole contents of a hernia is an interesting condition and one which at times severely taxes diagnostic skill. The question which first arises is as to how the appendix has come to enter a peritoneal pouch protruded beyond the abdominal wall. The normal appendix, some three or four inches in length, with a complete meso-appendix, is free to move within the abdomen within a certain range around its attachment to the cæcum, but it cannot be brought down to, much less forced or dragged through, either the right inguinal or right femoral ring. One of two conditions, then, is necessary for its descent. In the first place it may be considerably in excess of its usual length. This can be either the outcome of congenital elongation or of a stretching the result of adhesion. In the second place the cæcum may be abnormally free because of the presence of a long mesocæcum, with the result that the appendix may thus approach dangerously near to a hernial aperture.

A further point comes up for investigation in the query whether the appendix alone can be the primary and the final contents of a hernial sac. It is undoubtedly possible for it to be extruded into the sac of a so-called congenital right inguinal hernia, for in such a case there is a naturally patent processus vaginalis into which any viscus lying near may be forced. It is certainly somewhat difficult to understand how such a small part of the alimentary tract, having so little of surface area, would be able of itself to form a sac by pressure. But, on the other hand, is it actually necessary that there should be the special and active distending force of a particular viscus in order that an acquired pouch of peritoneum may be produced?

---

[3] Appendicitis, 1900, p. [illegible]

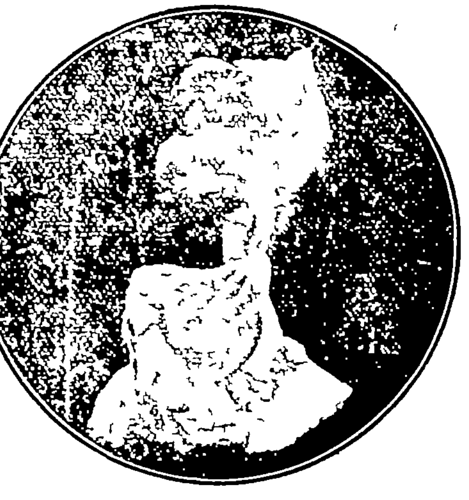
It does not require any very resistant organ to act in the production of a pouch—in fact, it may be true that no pressure of any individual viscus is absolutely needful. Some sacs with very narrow necks and yet apparently of acquired origin have but an extremely thin process of elongated omentum lying within them, and surely this would seem of itself less able to aid by pressure in the formation of a protrusion of the serous membrane than even the appendix. If, however, it is necessary to suppose that other of the abdominal contents besides the appendix have been the cause of the hernial sac, it is difficult to account for the very small pouches, and these often with narrow necks, which are found not infrequently as the coverings of prolapsed appendices. Doubtless this argument is open to the rejoinder that it is quite possible for the original multiform contents of the sac to have been reduced all but the appendix (which might alone have become adherent) and then for the mouth and neck of the sac to contract around the small structure passing through them, and beyond this it is perhaps feasible that strangulation, or, at least, some constriction of the appendix, may thereby occur. Or, again, the appendix might slip into a sac which had not previously contained it but which had been occupied by some other viscera.

The appendix when herniated is liable to a number of changes, some of which are peculiarly interesting and others of the gravest import.

Elongation.—Elongation is almost invariably present. The normal or average length of the tube is often given as about four inches, but the appendix may vary from one inch to nine or more inches. This lengthening, as has been remarked, may be the outcome of traction upon the tube, either by its being repeatedly nipped in the hernial ring or by its being adherent within the sac. Moreover, an appendix may be congenitally longer than usual; this fact itself may predispose to its protrusion. With this elongation there is sometimes an accompanying diminution in the calibre of the tube in its whole length or only in that part which still lies within the abdomen.

Adhesions.—Adhesions may form and they seem to be of comparatively common occurrence. Indeed, the appendix would appear to be proportionately more frequently adherent than any other viscus found in a hernial sac. These adhesions are probably always the result of local inflammation and it is a well known fact that an abnormally placed appendix is very liable to attacks of an inflammatory nature. In these cases of adhesion the appendix may be found attached to the margins of the mouth of the sac, with the extremity free in the body of the protrusion, or the tip alone may be the portion adherent, or, again, its whole length may be attached. This adherence, moreover, will bring about irreducibility and may further lead, as above stated, to elongation and thinning of the tube. Possibly it has also to do sometimes with the onset of another attack of inflammation by producing some kinking of the tube or by obstructing the exit of secretions from its lumen into the cæcal cavity. Lastly, the blocking of the mouth of the hernial sac may be so complete as to shut its interior off from the abdomen and thus to bring about the formation of a hydrocele of a hernial sac.

FIG. 10.



Hernia of the vermiform appendix into a right femoral sac (St. Bartholomew's Hospital Museum).

Cystic dilatation.—A cystic dilatation of the protruded portion has been found in several cases. Within the abdomen such a condition may also be found and there it would appear to be due to blockage of the lumen of the tube, either by contraction or by constriction or by kinking. Precisely the same may occur in a hernial sac. The mucous membrane of the tube contains glands which are continually secreting and if obstruction to the overflow of this secretion into the cæcum exists a cystic dilatation will result.

Inflammation.—Inflammation in a hernial sac is decidedly common, just as it is when the appendix retains its normal position. The causes of these inflammatory attacks are probably exactly similar to those of inflammation occurring in the appendix when it is in the abdominal cavity. It has been suggested that a truss worn over an adherent appendix is very likely to produce injury and thus cause inflammation and possibly this may account for a small proportion of the cases. As in the abdomen, so in the sac of a hernia, perforation of the appendix may be a termination of the inflammation and this may lead to symptoms which are very like, if not identical with, those ordinarily said to be the outcome of strangulation of the tube within the sac. In many of the recorded cases it was stated that there was a sudden onset of the symptoms and that there was local pain, also vomiting, and in some distinct constipation. These, of course, are symptoms which might well be put down to strangulation, and, therefore, intestinal obstruction, not so complete certainly as in instances where strangulation of a loop of intestine occurs, but similar in every detail to those which are in evidence when appendicitis is present within the abdomen. In this latter condition there is wanting any cause of strangulation of the appendix, though there is evident inflammation of the tube.

Strangulation.—Strangulation of a true nature no doubt does sometimes occur when an appendix is protruded, though I venture emphatically to assert that this is much less common than is usually thought to be the case. It may be brought about in at least two different ways. In some cases the contraction of inflammatory tissue outside the sac has seemed to be the real cause, but more frequently it appears that the appendix has been forced into a sac with a very narrow mouth, particularly into that of a so-called congenital inguinal hernia. Here the strangulation will be the result of the direct pressure of the tissues around the neck of the sac. In whatever way produced the symptoms which follow are, as has been stated, hardly those of true intestinal obstruction, but rather similar to those occasioned by a partial enterocele, by strangulation of Meckel's diverticulum, and sometimes by a prolapsed and nipped ovary. Usually on opening the sac the appendix is readily recognised, but at times owing to the presence of many adhesions, with, in fact, a matting together of the tissues, it is difficult to be sure as to the structure which is being dealt with. The appendix has been mistaken for the sac wall itself greatly thickened, for a second sac within an outer one, for the Fallopian tube, for Meckel's diverticulum, and even for the urinary bladder. The elongated form, the presence of its free extremity, and its small size as compared with other hollow viscera all serve to differentiate the appendix. The methods of treating the organ vary according to the condition in which it is found. If an operation for the radical cure of a non strangulated irreducible hernia is being undertaken and the appendix is found in the sac it may be returned to the abdomen, or it may be amputated in the usual manner and the stump returned within the peritoneal cavity, a line of treatment which, from its safety in the present day, is certainly the better. If, however, the tube is found adherent, and especially if not of natural size, it is well to free it from its attachments and to remove as much of it as can be readily drawn down into the sac.

ISOLATION HOSPITAL FOR TROWBRIDGE.—The Trowbridge and district joint isolation hospital committee has decided to erect a new hospital at an estimated cost of about £7000.

The Lettsomian Lectures

ON

E CONDITIONS WHICH MODIFY THE CHARACTERS OF INFLAMMATIONS OF THE SKIN, AND THEIR INFLUENCE ON TREATMENT

livered before the Medical Society of London on Feb 16th and March 2nd and 16th, 1903

By H RADCLIFFE CROCKER, M D, F R C P LOND,

ICIAN TO THE SKIN DEPARTMENT UNIVERSITY COLLEGE HOSPITAL.

LECTURE III.[1]

Delivered on March 16th.

MR. PRESIDENT AND FELLOWS,—The internal treatment of inflammatory diseases of the skin rests, so far as our knowledge permits, on the same foundation as that of other organs—viz., an accurate diagnosis and full knowledge of the etiology, pathology, and prognosis of the disease with which we have to deal Unfortunately, the gaps in our knowledge under these heads are at least as wide as they are in any other department of medicine, and we have to try to fill them up to the best of our ability with the help of remedies which experience has taught us to be of service in this or that form of dermatitis, whether we understand the *modus operandi* or not. I hope, however, in my previous lectures that I have afforded some assistance in estimating the factors to be considered in coming to a conclusion as to the line of procedure So far as the treatment depends on the general principles of medicine it is not for me to presume to lecture you, I would only like to say that, being a firm believer in the theory of the frequent absorption of toxins and ptomaines from the intestines and other organs, I am as strong an advocate for clearing out the *primæ viæ* as ever our forefathers were who with their emetics and purgatives cleared out their patients so thoroughly whatever their complaint might be that it gave occasion for the laity to rail against the profession, as in the uncomplimentary couplet attached to the name of the distinguished physician in whose honour these lectures were founded. As their patients were for the most part gross feeders and heavy drinkers they had some excuse for their drastic procedures, while we, having more definite aims, are able to avoid the excesses of these stalwarts in medicine and are content to remove whatever fæcal matter the intestine contains and to diminish portal congestion and with intestinal disinfectants and the requisite precautions as to diet endeavour to prevent the formation of fresh toxins

For the liver and kidneys similar principles are to be carried out and the success of many of the spas, like Contrexéville for instance, really depends on its being a method of washing out the liver kidneys, and intestines with very dilute alkaline fluids, but copious draughts of aerated distilled water are an excellent substitute for those persons whose powers of elimination are not up to the proper standard while their purse will not enable them to go to these spas, and sipping very hot water is also a familiar expedient although overdone by the laity, whose zeal being not according to knowledge is only too apt to abuse the remedy of the hour by indiscriminate use.

In senile eczema and pruritus this washing out of the liver and kidneys is especially important and is often the means essential to success.

ARSENIC

When we come to the specifics naturally arsenic has first to be considered both on account of its long established position and because of its employment for all sorts and conditions of skin eruptions by a large majority of the profession. Yet I venture to say that it is regarded by dermatologists generally as a most disappointing drug and that its rôle gets more restricted as their experience widens.

How does arsenic act? Our knowledge is far from complete, but there can be little doubt that it has a direct action on the epithelial cells and also on the vaso-motor nervous system centrally or peripherally and on the periphery of the cerebro-spinal nerves. In order to get the good results without the bad we must have definite aims, its local action is best seen in the patches of chronic subacute scaly eruptions such as psoriasis and some forms of lichen planus.

That its action is really local on the diseased area for which it has an elective affinity is shown by its effect on the patches of psoriasis. While it often removes any particular patch it does not prevent the evolution of another in its neighbourhood. There is also more pigmentation left in patches treated by arsenic than in those removed in other ways. That it is not a specific in psoriasis is shown by its not being in any sense prophylactic, and if given when the eruption is evoluting rapidly, so far from preventing this evolution it actually makes it come out more rapidly It is, therefore utterly useless for patients suffering from psoriasis to go on taking the drug year in and year out, as many do in the hope of warding off their enemy They not only fail to do this, but they bring upon themselves dangers and disfigurement from the direct effects of the drug itself. The disfigurement, as is well known, is due to a sepia brown pigmentation which, in my opinion, is due to the actual deposition of the metal itself in the skin When used only for a moderate time this pigmentation is limited to the area of psoriasis, for arsenic appears to pick out morbid tissue, of this I had an illustration in a patient suffering from psoriasis of the nails who said to me "Since I have taken the medicine I have had a pricking sensation at the root of the nails."

The general pigmentation induced by arsenic may be recognised by its sparing for some time the neighbourhood of the hair follicles which appear as white dots on a dark ground but eventually they get pigmented also More important even than the pigmentation is the thickening of the horny layers, chiefly of the palms and soles which ensues from its excessive use This also is recognisable in the early stage, as it is at first a nodular thickening round the sweat orifices or actual horny warts may be formed but after a time the whole surface is thickened and levelled up into a horny plate over the whole palm and sole except the arch, accompanied by and perhaps in many cases caused by, hyperidrosis. Besides the inconvenience and unsightliness of this keratosis it is liable as Mr J Hutchinson first pointed out, to lead to epitheliomatous growth from these warty thickenings.

In the following case the man had psoriasis in his youth for which much arsenic was given until he had horny hypertrophy of the palms. He remained free from psoriasis for thirty eight years but the keratosis never went away and one of the warty growths became epitheliomatous and was removed, it recurred, but a wider operation cured it That such a consequence should ensue, even so many years after the cessation of the drug, is a warning that it is not to be given indiscriminately and in a haphazard fashion, but its effects must be carefully watched and sufficient periods of rest given. At best it is a slow remedy as far as psoriasis is concerned.

In some of the worst forms of lichen acuminatus it has also been successful, but for that complaint we have now a better remedy than arsenic, its action in both this and lichen planus being probably directly on the epithelium of the diseased area. Its other action is through the nerves and is wholly or mainly peripheral.

Recurrent angio-neuroses such as some of the erythemata which recur at short intervals (not those which only recur seasonally) are often controlled and sometimes cured by the steady administration of arsenic in moderate doses but continued for a long time Erythema hæmorrhagicum is one o these, in this eruption at intervals of a few days, or a few weeks the patient has what appears to be an erythematou eruption in spots from a sixth to half an inch in diameter but they are unaffected by pressure from the onset and som of the lesions acquire a purpuric appearance, it come chiefly on the legs but in a minor degree on the upper limbs It is probably caused by a toxin acting on the vaso-moto nerves but arsenic often controls it and may cure it. In on of my cases, a musician in an orchestra had an outbrea whenever he had been kept up very late, although I coul not explain why this should be I regarded the eruption a of vaso motor nerve origin and gave him liquor arsenical in five-minim doses which stopped the renewal of th eruption as long as he was taking it and ultimately cured the morbid irritability of the affected nerves.

---

[1] Lectures I. and II were published in THE LANCET of Feb 21st (p. ,31) and March 7th (p 640) 1903 respectively

In recurring sweat eruptions it is also of great value The eruption illustrated by the following case was a form of miliaria exactly like the red gum on infants. The patient, a railway porter, had suffered from it for eight years, whenever he got overheated, as he necessarily often did at his work , arsenic controlled and partially cured it after it had been taken for a long period, but I scarcely expect that after so many years it will be completely cured. Another recurring sweat eruption in the form of small vesicles along the sides of the fingers, from which so many people suffer in the summer, is definitely relieved by arsenic. So also is chronic urticaria not dependent on digestive disturbances but in this the dose should be small and long continued Pemphigus and dermatitis herpetiformis are generally controlled and sometimes cured by arsenic But I am far from regarding it a specific for pemphigus as Mr Hutchinson does, as it often fails conspicuously even to have a controlling effect. In all these the action is through the nervous system, chiefly the vaso motor, either peripheral or central Its preventive influence over bromide or iodide eruptions has already been mentioned

While the above pretty well covers the ground in which it is beneficial or curative, its frequent indiscriminate use renders it more important to point out where it is useless or injurious As an internal remedy for eczema in any stage I have very little faith in it except in chronic scaly patches which can, however, be more efficiently dealt with by suitable local treatment, while in the acute and subacute discharging eczemas it is quite useless in my opinion No doubt if it is given in every case with good local applications a fair number of cases will get well, but so most of them would if burnt sugar and water were given with the same local treatment, but in none of the obstinately recurring cases, without any apparent cause for the exacerbation, which often baffle us for a long time has arsenic ever helped me in a single case that I can recollect and I now scarcely ever give it in eczema, either acute or chronic It should never be given where there is already gastric irritation, as in acne rosacea, urticaria from dyspepsia, &c It should not be given in the evoluting stage of psoriasis and, as a rule, not when there is great hyperæmia, as it often aggravates the pruritus and congestion , indeed, with the exception of bullous eruptions, it is seldom advantageous in acute inflammations of the skin and often acts injuriously

A few words as to its administration. It may, as you know, be given as a liquid, a solid in pills, or by injections Injections are painful and are only, in my opinion, to be given for sarcomata , the Asiatic pills, which are arsenious acid and black pepper, are much used on the continent and are useful if the patient has to be out all day, but, on the whole, the advantages are all in favour of the time-honoured Fowler's solution, which can be given freely diluted and is thus less likely to give rise to gastro intestinal irritation. The cacodylate of sodium is still on its trial. It is by no means certain that its action is the same as the other forms of arsenic and it is not so free from danger in the recommended doses On the whole, I should reserve it for hypodermic injection for sarcoma, in which one is justified in taking some experimental risks All the other preparations of arsenic are I think, inferior to Fowler's solution The arseniate of sodium is said to be more easily tolerated by the stomach, but probably the real explanation is that the atomic weight of sodium is less than that of potassium and requires less arsenious acid to satisfy a given quantity of it, so that 10 minims of liquor sodii arseniatis only contain the same amount of arsenious acid as there is in five minims of Fowler's solution In no case should it be given for many months in succession without intervals from time to time being afforded for its elimination.

SALICIN AND SALICYLATES.

These drugs were introduced by myself into dermatology and I can state with confidence that they have been conspicuously successful in a large number of skin diseases. At first I used the salicylate of sodium, but finding that it disagreed with rather a large proportion of patients I tried salicin and found it quite as good as far as its action on the skin went, while it seldom disagreed with the digestive or other organs It has not so much depressing action as the salicylates, very rarely produces headache, and may always be combined with nux vomica if there should be any depression. In very exceptional cases I have seen it produce an erythema which is more frequently seen with the salicylates Salicin is said to break up in the organism into salicylic and carbolic acid and it is possible that these substances in a nascent condition in the blood may exercise either microbicide action or at least hinder the multiplication and development of microbes. At all events, it is most likely to be successful in those diseases in which there is a strong probability that they are of microbic origin, such as psoriasis, lichen planus, and pityriasis rosea On the other hand, it has no direct effect on any form of eczema and I only give it in that disease when I want to produce an effect on the liver and then the sodium salt is preferable. Speaking generally, it covers the same ground as arsenic and has in some respects advantages over that drug Thus it may be given during the developing stage of psoriasis and often checks the outbreak, while I have never seen it increase the development as arsenic often does. In giving it in psoriasis it must be given in full doses, 15 grains three times a day to begin with, and it may be increased to 20 or even to 30 grains three times a day, though I seldom give more than 22½ grains , in these doses in some patients it produces constipation which has to be counteracted It succeeds best in hyperæmic and extensive outbreaks, is of but little use when there are only a few chronic patches, and has not any striking effect on the scalp eruption It appears to act by diminishing the hyperæmia, the patches become paler the scales become looser and gradually cease to re form, and the patch becomes a circle, and even this gets broken up and only fragments remain which are best removed by local means. Its effects, of course, are best seen when no local treatment is simultaneously employed, but if local applications are used they should not be of a stimulating character, otherwise the internal and external medicaments are opposing each other In the great majority of cases its action is much quicker and it is successful in a larger proportion of cases than arsenic.

Of course the drug does not succeed in all cases—nothing does , but in 100 consecutive cases it would be beneficial probably in 75, it would have a markedly good effect in about 50, and in from 20 to 30 it would effect a cure, in an extensive case in from one to three months. I do not lay these figures down as absolute but as a general impression after a very extensive use of the drug Some have been disappointed in its use either from prescribing it too timidly—i.e , in five grain or ten grain doses—or in expecting to see a striking effect result in a week or two, which is naturally exceptional, or in trying it only in a few cases and taking a few failures as an indication of its value

In lichen planus the number of successes of salicin is not so great as in psoriasis, but that may also be said of arsenic or biniodide of mercury, but in some of the acute generalised cases the result has often been most satisfactory and even rapid, as in the following case where the disease was very acute and severe A man, aged 30 years, was sent to University College Hospital by Mr Percy Rose of Barking with general lichen planus which had developed rapidly latterly but had been present to some extent for eight months. It involved every region of the body, affected the mouth extensively and was complicated by keratosis palmæ and hyperidrosis. He had taken Fowler's solution in five-minim doses for a month without any improvement before he went to the hospital. Salicin in 15-grain doses three times a day, which in three weeks was raised to 20 grains was prescribed without any local application. Improvement was manifest in the first week, the enormously thickened skin of the palms and soles was shed in large pieces in three weeks, and in about six weeks the whole eruption had disappeared except that, as is usual there was deep pigmentation on the site of the lesions. Such a rapid cure is exceptional, as the course of lichen planus is usually excessively slow in its involution though often rapid in evolution, and no doubt there are many cases which are unaffected by salicin, but the same may be said of any method , the failures are more numerous than the successes for any one drug

Of pityriasis rosea, it may be said that it tends to get well of itself in from four to six weeks, so that it is difficult to say that a cure is the result of treatment or spontaneous, but there are cases which go on much longer, even several months, and I have repeatedly seen in such cases involution commence in a week or two after commencing the salicin This could scarcely be an accidental coincidence

With regard to bullous eruptions I have repeatedly known salicin to be successful both in pemphigus and in dermatitis herpetiformis even when arsenic has been well tried and failed, so it is always worth while to administer it in both these diseases which are sometimes most resistant to every treatment and can perhaps only be controlled as long as the drug is being administered. It has also been conspicuously successful in some of the more acute or widespread forms of lupus erythematosus which although not a simple dermatitis resembles one in many of its features. This does not exhaust all the possibilities of the drug or set of drugs which I regard with more confidence than arsenic for the diseases which I have mentioned, for its range is wider and it gives a higher percentage of successes, but like other drugs it has its failures.

It is probable that similar drugs which break up in the organism may be found to give similar effects. Aspirin, the acetic ester of salicylic acid, is one of these and I have had a few cases of psoriasis successfully treated by this drug which has been introduced as a rival to the salicylates. In a very obstinate and extensive case with gouty swelling of the finger joints not only did almost all the psoriasis clear up, but the deformity of the fingers improved considerably. Its slight solubility—five grains to the ounce—and the comparatively high price militate against its extensive employment.

THYROID EXTRACT.

Thyroid extract, which was first brought prominently into notice by Dr. Byrom Bramwell for skin eruptions, came in with such a flourish of trumpets that it raised too great expectations and in the disappointment which followed the reaction has been too great and it is almost lost sight of as a therapeutic agent in dermatology. This I think, is a pity, although it must be content with a lower place than was at one time expected it is a most valuable therapeutic agent. It was for psoriasis that most was expected of it and no doubt some very striking results were obtained, but the uncertainty of its action, not only in different cases but in different attacks in the same patient, and the fact that it not only sometimes failed but actually did harm in some instances, have made many throw it aside. The evils inherent in the substance itself can be avoided by not giving it to elderly people or to persons with weak hearts, by beginning with a single five grain dose and taking two or three weeks to reach 15 grains a day, and never to give more to patients who are not under constant observation. In psoriasis it should never be given when the disease is evolving as I have seen the most disastrous development in such cases. In young robust persons, with an extensive eruption which has reached its full development, it sometimes acts literally 'like a charm' and I have seen the eruption disappear more quickly than under any other internal treatment, but it must be admitted that such cases are exceptional and that it too often disappoints where *a priori* it might be reasonably expected to succeed.

There are other diseases in which thyroid extract is distinctly advantageous. Willan's and Hebra's prurigo is one of these, eczema on a congenitally ichthyotic skin as I have previously mentioned, in lichen acuminatus I have found it conspicuously successful, and finally, although it does not come under dermatitis, it has more beneficial effect on lupus vulgaris than any internal medication that has ever been given. It is a substance, therefore, to be borne in mind as a valuable medicament in selected cases, if given with due precaution and watchfulness to prevent thyroidism. Patients no doubt get thinner when taking it and they require an interval every now and then if it is to be given for a long period as in myxœdema and lupus vulgaris.

ICHTHYOL.

This drug is given internally to a limited extent and has been sometimes beneficial in some hyperæmic diseases like acne rosacea. I have found it chiefly useful in some of the sweat inflammations. Its successes are not very numerous or conspicuous, but it is one of those drugs which break up in the organism and its sulphur constituent is eliminated by the skin of which an ocular proof will be afforded if a lead lotion is applied while the patient is taking ichthyol the pores of the skin speedily turning black from the sulphur of the ichthyol combining with the lead lotion.

QUININE.

There is one more drug of which I have a high opinion in certain forms of extensive dermatitis and that is quinine. It must be given in large doses (from five to ten grains) and the method of administration is important. This should be in an effervescing citrate of potassium mixture. In this way it rarely disagrees with the patient or produces cinchonism if the bowels are kept open, while if given in the ordinary way with sulphuric acid large doses are seldom tolerated. I prescribe it chiefly where there is extensive or universal dermatitis, especially in pityriasis rubra. Dr. J. F. Payne advocates it in lupus erythematosus when acute or widespread. It is an alternative drug in some cases of pemphigus and dermatitis herpetiformis when arsenic and salicin have failed, but it is not equal to either of those drugs in the number of cases for which it is suitable.

SUBCUTANEOUS AND INTRA-MUSCULAR INJECTIONS.

Subcutaneous and intra-muscular injections of various drugs obtain a growing importance in dermato-therapeutics. Salts of mercury hold the first place and no doubt as yet their chief employment is found in syphilis and leprosy, but I will not dwell on their value for these diseases as they do not come within the scope of these lectures, but in some obstinate and extensive cases of psoriasis, in which other internal medication has failed and when the patient cannot lie up for efficient local treatment, I have had very gratifying success with injections of mercury salts. These injections should always be intra-muscular and not subcutaneous, the latter are much more painful and are liable to produce sloughs at the site of injection. In my opinion the soluble salts are preferable, as they are less liable to produce severe and even dangerous salivation than the insoluble salts with which there have been several accidents, although really a very small number compared to the thousands of injections given.

The perchloride and sozoiodolate are the salts chiefly employed, the latter is the best as it is equally efficacious and less painful. The dose is a quarter of a grain dissolved by the aid of one-third of a grain of iodide of sodium in 20 minims of water, injected into the buttocks once or twice a week. As the biniodide and perchloride of mercury by the mouth have proved useful in lichen planus, probably intra-muscular injections would be still more efficacious but they should not be employed until other means have been thoroughly tried as the injections are painful and would probably not be tolerated unless the patient had tried and failed to get relief by other treatment. Mercurial injections have also been used for lupus vulgaris with some measure of success, but there are other means at our disposal for this disease.

Arsenical injections have been occasionally used for chronic inflammations of the skin such as would be benefited by the same drug given by the mouth, but the results have not been sufficiently good to warrant their being recommended and their only use seems to be for sarcomatous tumours as first recommended by Köbner. Mycosis fungoides has also undergone temporary amelioration with them. The potassium salt is much more painful than the sodium salt and this is the one to be preferred and here also intra-muscular injections are less painful than subcutaneous ones.

Cacodylate of soda and the similar body called arrhénal have not, as Sir Thomas R. Fraser has shown, justified their laudatory introduction.

Subcutaneous injections of thiosinamin were first recommended by Hans Hebra for lupus vulgaris, but other methods were found to be superior and it was soon abandoned for that, it has, however, been found remarkably useful for keloids and hypertrophic scars, and I can bear personal testimony to its value. Here is an example. A boy, aged 14 years, was burnt by a chemical and a keloid followed in a month or so oval in shape, one and a half inches long, and situated on the forearm. It was excised by the family medical attendant and primary union was obtained, but a keloid soon formed in a line with the incision and in the suture holes and in three months from the operation was three and a half inches long and half an inch wide and was getting more prominent and irritable, weekly injections of a 10 per cent. thiosinamin solution were recommended and in two months after seven injections the major growth was flattened and had lost its purplish tint and several of the suture keloids had disappeared.

In hypertrophic scars I have had very good results. In a girl with contracted thickened bands across the elbow of long standing and consequent on a burn, the thickening entirely disappeared and the mobility of the joint was in great part restored. In another case in which there was a band all round the lower jaw, raised up a third of an inch with numerous projecting spur like processes, very considerable improvement was produced, the growth being much flattened, but the patient was unable to continue to attend the hospital, so that the cure was incomplete. Its mode of action I am unable to explain. The 10 per cent solution in glycerine and water usually recommended cannot be kept in permanent solution, but 8 per cent. solution with 20 per cent glycerine and the rest water, the solution being effected with a gentle heat, remains dissolved. The injections are well borne by the patients and are not, therefore, very painful nor do they produce any bad effects, local or general, in my experience.

But sufficient has been said upon specifics and it should be remembered that in a large proportion of cases their administration is an indication of failure to understand the true etiology and pathology of the disease and that we are driven, therefore, to resort to empirical remedies This is not a reason against them if we have first used all our available knowledge in the investigation of the case on which to found a rational treatment, but this is unfortunately possible only in a very limited number of cases and very often in the history of medicine the empirical remedy has justified its use by its curative successes long before the theory of its action was understood, the use of quinine in malaria is a striking example. Still, we are beginning to get a glimpse of the *modus operandi* of these so called specifics, sometimes we can fairly regard them as microbicides in the blood, or as antidotes to autotoxins, or as preventing the formation of these toxins, and in proportion as we are able to use these drugs on a rational basis our successes in their employment will increase, while it is an immense satisfaction to find that having made a correct pathological diagnosis we are able to insure that the treatment founded upon it has also been the correct one.

There are certain general measures to be adopted in all forms of acute and widespread inflammation of the skin quite irrespective of what the diagnosis may be, first of these come rest and equability of temperature. Although urticaria is not a true dermatitis, it is not far off from the early stage of it and may be used as an illustration of it Jacquet enveloped in cotton wool, one arm only of an urticarial patient, the urticaria came out as before on the uncovered arm while there was none on the covered one. The importance and value of putting patients in bed who have an extensive dermatitis were borne in upon me very early in my career Wishing to observe the influence of certain drugs on different inflammations of the skin I took the patients into the hospital and gave them no active medication until the influence of transference from their home to the hospital had been eliminated, and I found to my surprise that in many cases the improvement was so great that no trial of the drug could take place. The case of a postman with a general erythematous eruption which had been present for several months without improvement made a strong impression on my mind. I put him in bed without any other treatment and in three days the eruption disappeared and did not recur

The true prurigo of Willan and Hebra, which is proverbial for its obstinacy, is at once relieved by placing the patient in bed, and in a week some of the most severe and distressing features in a great measure will have subsided. When the whole skin is *hors de combat* as in pityriasis rubra it is not only desirable but positively imperative that the patient should be in bed and I will not undertake the responsibility of such a case if the patient refuses to lie up completely Some years ago a man came to me with this disease very extensive but not then universal, his face being spared. I urged him to lie up at once, but as he had an invitation to stay in luxurious quarters he said that he would defer treatment until after his visit. I could not hint that he was not a very desirable visitor (for when he undressed the scales fell down like a theatrical snowstorm) but I tried in vain to dissuade him from such a dangerous procrastination and a few weeks later I heard that he had died, it was said from congestion of the kidneys I believe that his life would have been saved if he had at once taken to his bed and had been efficiently treated from the first. Even when a dermatitis is not sufficiently extensive to necessitate the patient lying up it is often of the highest importance to avoid sudden changes of temperature and it is a matter of common observation in a patient with eczema, or, indeed, almost any acute dermatitis, especially on exposed parts, that to go out in a north east wind or to ride in an open carriage on a windy day is an almost certain way of producing an exacerbation of the disease. In persons still more sensitive, such as those who have urticaria, the sudden change of going in winter from the usually warm sitting room to a cold bedroom will often determine an attack

LOCAL TREATMENT

I have pointed out the line of the local treatment for the several affections which we have been considering as we went along and there only remain a few general principles to consider One is that in all acute inflammations the applications should be continuous. An ointment or a lotion applied for a few moments two or three times a day will be seldom of any service except for a slight inflammation. The continuous application insures that the medicament will be in the closest contact with the diseased surface, that the part will be guarded against external microbic invasion, that it will be protected from air and water, and that it will be to a great extent at rest and at an even temperature. Continuous applications must necessarily be of a mild character or they will increase the inflammation, lead, zinc, of what the Germans call indifferent applications, such as simple unguents and oil, being the kind of medicaments chiefly employed

Most microbicides, such as tar, mercury and silver salts, chrysarobin, ichthyol, &c, are more or less irritants and should be applied for a short time only and of a dilution adapted to the intensity of the inflammation irrespectively of its name, and it is often safer to try the application on a small area at first until the right strength and best form of application have been ascertained These drugs can often be combined with soothing astringents, such as zinc oxide or zinc oleate, to mitigate any irritant action and it is by no means to be inferred that the stronger the proportion of the most active ingredient the more beneficial will be the prescription. In the case of chrysarobin, for instance, such very small proportions as from one to five grains of chrysarobin to an ounce of zinc ointment will act admirably in some subacute cases of eczema or in the more acute forms of psoriasis, while in stronger proportions the disease would be aggravated The same may be said of many tar preparations. In chronic indurated patches higher proportions may be necessary In the case of tar in the milder forms of eczema, while it is often one of the most efficacious remedies we possess—so much so that one gentleman of high repute in dermatology acknowledges that tar and lead lotion is his one remedy for all forms of eczema, the proportion only varying to each other and to the dilution—yet tar is one of the most difficult remedies of which to be sure of the suitability in cases of eczema, a premature use or too strong a proportion lighting up again an inflammation just when it seemed to be subsiding satisfactorily It should, therefore, be ordered in small quantities at first and in a small area and for a short time in cases of eczema, while in psoriasis it can be adapted to almost every case by a little management and even be used at the full strength of the Pharmacopœial liquor picis carbonis, if a soothing lotion be immediately and continuously applied afterwards.

In choosing a local remedy it is necessary to have a definite aim Is it the hyperæmia that is to be subdued, the exudation to be dried up, or the suppuration to be stopped? or is it some micro-parasite that is to be destroyed without increasing the inflammation? Then the extent of the area affected is to be taken into consideration, as the medicament might be, like mercury or pyrogallic acid, dangerous if applied to a large region though quite adapted for a small area.

Further, there is a complicating factor of which it is not possible to predict, unless from previous experience of the patient—viz, idiosyncrasies towards certain drugs, either external or internal and the variable reaction to remedies of certain skins This is especially common in the acute forms of eczema—a remedy which is like a balmy breeze to the majority of patients acting like the blast of a furnace to some others in whom the character of the inflammation appears to be precisely similar No doubt experience diminishes the number of such mistakes, but the most experienced have many humiliations to put up with in this connexion It is for this reason if for none other that it is wise never to start with strong remedies but to work up to them as the knowledge of the patient's peculiarities increases

Many of the indications can be successfully met by recognising the character of the inflammation without making an exact diagnosis, an acute psoriasis and a subacute eczema, for instance, often requiring the same local treatment, but in others an accurate diagnosis is essential, as in the inflammation excited by scabies in clean people, which is so often erroneously treated as an eczema, or in not recognising that impetigo contagiosa is secondary to some previous itching lesion such as urticaria, prurigo, animal parasitic irritation, &c. It is, however often desirable and even necessary to remove the secondary lesions first in order to pave the way for the most effectual means of treating the primary eruption

GENERAL DEDUCTIONS

The general deductions which may be drawn from the subject we have been considering are —That a large proportion of inflammatory diseases of the skin are of compound origin That there is frequently a microbic element and that this too may consist of more than one kind of microbe superimposed on another such as the staphylococcus aureus on the streptococcus pyogenes the staphylococcus on the seborrhœic mioro-bacillus, the seborrhœic micro-bacillus on the bottle bacillus &c That not only do these several mixtures produce different forms of dermatitis, but that even the same microbe may produce different forms according to its mode of implantation in the skin. That the microbic element generally requires a suitable soil for its successful implantation and propagation. That this soil varies with the age of the individual and the kind of skin he possesses of which the modifications may be congenital or acquired, certain of the tissue proclivities being probably hereditary That intestinal and probably other visceral toxins and ptomaines play an important and often unsuspected part in producing many forms of eruption and even that many supposed gouty eruptions are really of toxic origin from the generally present intestinal catarrh. That many of these toxins act through the vaso-motor nerves, central or peripheral rather than directly on the skin, though they may act directly on that also That the cerebral nervous system acts chiefly as a controlling influence over the sympathetic system as regards the intensity of the eruption. That with very few exceptions the nervous system, whether vaso-motor or cerebral, exercises but little influence on the character of the eruption though it does on its distribution and intensity That the character of the eruption is mainly due to individual peculiarities or proclivities of which we can often only chronicle the result without being able to explain it That while with apparently the same etiology different eruptions may ensue in different individuals, in recurring eruptions in the same individual there is remarkable constancy in the characters of the eruption and in its time, place, and mode of development. That many general eruptions are for a long or short time of local origin, occupying only a small area before generalisation. That other serious affections start from apparently trivial causes, such as seborrhœa, a superficial pustule, &c and that it is important, therefore, to treat affections of the skin in as early a stage as possible, as most inflammatory eruptions have a much greater tendency to further development than they have to spontaneous involution. That the principles of treatment depend on the due appreciation of the relative importance in any one case of the microbic, the personal, the nervous system, and the toxic elements, and that so far as our knowledge extends the general principles of medicine apply to them, but that inasmuch as our power of estimation is often at fault we have to fall back on certain so-called specifics which experience has shown to be of service in certain conditions. That the most reliable and comprehensive specifics are arsenic, salicin, thyroid extract, quinine in large doses, and iodide of potassium, the first two have a very wide range as compared to any others. That except as regards pustular eruptions and those demonstrably of micro parasitic origin the character of the local treatment depends comparatively little on the diagnosis of the particular kind of dermatitis, the extent, intensity and localisation of the inflammation being the most important elements. That in employing microbicide treatment in superficial and widespread eruptions the microbicide should not be irritating, or should at least be capable of being at once neutralised, otherwise the increased inflammation set up defeats the aim of the therapeutist and affords a favourable soil for further microbic development. It is in comparatively few circumscribed microbic diseases such as impetigo contagiosa, boils, and carbuncles that the microbicide is the sole curative agent. That in all wide-spread forms of dermatitis rest and equability of temperature are the most important and often the essential curative means. Finally, that in proportion as we study diseases of the skin in the same manner as we study diseases of other organs, we shall find that their treatment can be carried out successfully on the sound basis of pathology and that specifics will occupy a diminishing space in our armamentarium.

The statistics which I gave you in my first lecture show that the task of acquiring the power of diagnosis such as every practitioner should possess is not difficult in the majority of instances, as three-fourths of all cases of dermatitis are comprised under a very small number of diseases, but a considerable practical experience is necessary to grapple successfully with the variations which even these few common diseases present according to the several conditions we have already discussed, but attention to these points will gradually make this easier and will bring success which will add interest to the further study of a class of diseases which is a sealed book to many otherwise well-informed medical men, because they have not started on their investigation in a systematic manner

I trust that this brief *résumé* that I have given of a wide subject will be of some assistance to a serious study of the inflammations of the skin which will well repay the time spent upon it both by yourselves and him whom I must now call "your late Lettsomian lecturer"

A CASE OF ACUTE SPLENIC ANÆMIA TERMINATING FATALLY WITH GENERAL BACTERIAL INFECTION

BY HERBERT P HAWKINS, M.D OXON, F R.C P LOND,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT ST THOMAS'S HOSPITAL

AND

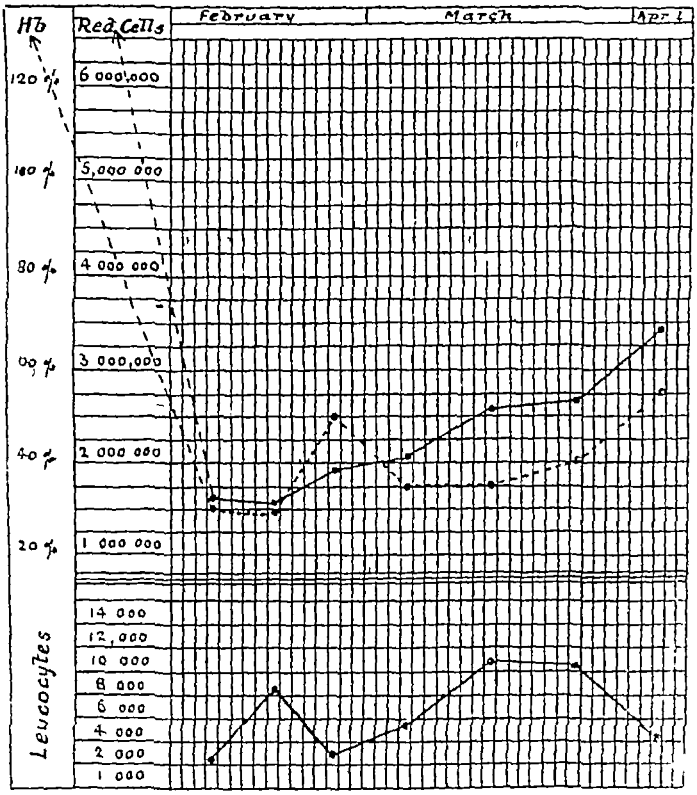
C G SELIGMANN M.B., M.R.C P LOND,
SUPERINTENDENT OF THE CLINICAL LABORATORY OF ST THOMAS'S HOSPITAL.

AN Italian *chef*, aged 37 years, was admitted into St. Thomas's Hospital on Feb. 7th, 1902, where he died two months later His previous history threw no light on the nature of his illness He had had no illness except slight indigestion occasionally had always been temperate, but had smoked about an ounce of cigarettes a day There was no history of syphilis or malaria or rheumatism, and he had not been in Italy for 28 years. He presented an odd appearance, for at the age of four years he was run over and his lower jaw was so damaged that some of the bone on the left side necrosed and was removed and at the age of 14 years he lost the sight of the left eye by an accident. His statement was to the effect that in January, 1902, having been previously in good health, he was admitted into the Italian Hospital suffering from pneumonia. The anæmia probably dates from this time, for on his recovery from the pneumonia he was sent to a convalescent home with the advice to return to the hospital later to obtain treatment for the blood state. After a few days at the convalescent home he began to experience difficulty in swallowing solid food, apparently through a dryness of the mouth, and becoming discontented on other grounds he left the home and was admitted into St. Thomas's Hospital.

On admission his chief complaint was a distressing feeling of weakness. But he stated also that he had difficulty in swallowing solid food, had to roll it about in his mouth before he could get it moist enough to swallow, and was frequently aroused from sleep by a choking dryness of his throat. There was some scarring over the lower jaw at the site of the injury which he had received in his infancy and the molars and the bicuspids had gone But the rest of the teeth were in good order, there was no apparent lack of saliva, and there was no apparent change in the buccal or pharyngeal mucous membrane, and, as a matter of fact, he never showed any difficulty in swallowing after admission, but gave play to a very considerable appetite He was rather thin and pale, with a slight yellowish tint of the skin and conjunctivæ. The spleen was considerably enlarged (post mortem it weighed 25 ounces), but its borders were always difficult to determine, owing to general fulness and resistance of the abdomen. The liver extended for two inches below the costal margin, as determined by percussion, but no clear signs could be felt. The heart was healthy but for a systolic murmur in the pulmonary area, the pulse was 102, small, and of low tension, and the temperature was 101° F The optic fundi were pale but healthy, the pupils were equal and active, and the knee jerks and plantar reflexes were normal. The shins were slightly œdematous The urine was strongly acid, brownish yellow, clear, with a specific gravity of 1018, and contained no albumin or sugar With the spectroscope it showed the absorption band of urobilin at F

During the first fortnight of his stay in hospital he improved considerably under the use of iron and arsenic. His temperature became subnormal, his appearance improved, the appetite was good and at times voracious, and he expressed himself as feeling quite well He gained three pounds in weight. During the second fortnight, however, his temperature began to rise, reaching 103° on two occasions, and coincident with this pyrexia there was profuse diarrhœa, there being on one day nine watery and rather offensive stools There was no blood or anything to indicate any necrotic process in the bowel and the diarrhœa was, in fact, attributed to the irritant effect of the arsenic The temperature fell to a subnormal point rather suddenly at the end of this period and during the third fortnight it remained subnormal with nearly normal stools a good appetite, and considerable general improvement. During the fourth fortnight the pyrexial attack was repeated. The temperature rose slowly at first, but soon reached 104° in the evenings and remained at about that level until death. At the same time the bowels again became very loose There was a tendency to sweat at night. The nose bled occasionally, the gums began to ooze, and the teeth became foul and clogged with blood He took very little food. The mind became obscured. The heart failed rapidly and rhonchi were heard over both lungs. During the last four or five days of life he became more and more yellow, eventually reaching the colour commonly met with in catarrhal jaundice. The urine preserved the characters already mentioned and containe no bile. Bile was always present in the stools During th whole course of the illness there was no alteration in th physical signs as regards the spleen and liver, but h complained occasionally of pain over the former The were no ascites, no necrotic process in the mouth, and n cutaneous or visceral hæmorrhage

CHART 1



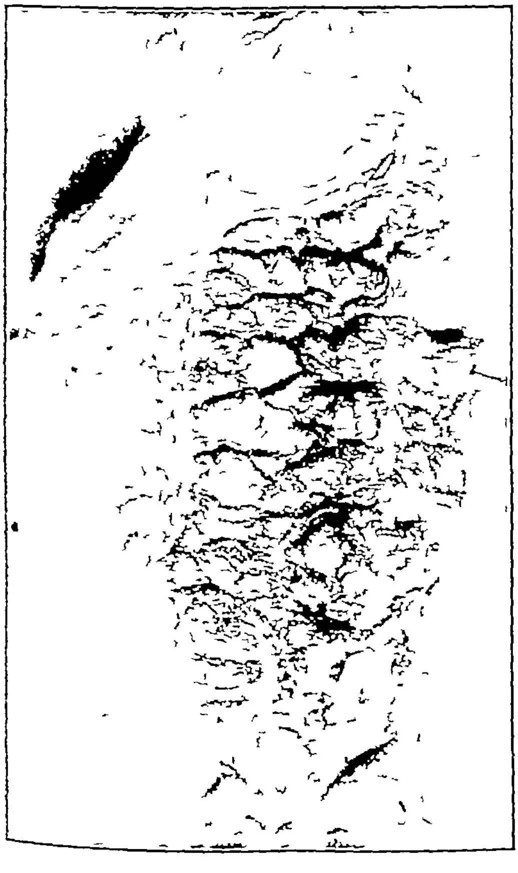
The state of the blood can be gathered from Chart It showed the type of secondary anæmia, the colour inde being below par (from 0 6 to 0 9) except on one occasio (Feb 24th), when it was 1 3. There were good rouleau formation and little, if any, variation in the size or shape the red cells, though on one observation (Feb 24th) a fe showed polychromatophilic degeneration. No nucleated re cells were ever seen There was no leucocytosis at any tim and the normal relative proportions of the different kin of leucocyte were roughly preserved, polymorphonucle neutrophiles varying from 62 to 80 per cent., lymphocyt from 18 to 35 per cent, and eosinophiles from 0 6 2 0 per cent A percentage of 0 6 of mast cells was note on two occasions Blood platelets were unusually abunda in one specimen. On three examinations marked leuc penia was found, the counts being 2200, 3000, and 40 respectively

Morbid anatomy —The liver weighed 67 ounces, th patient's weight at death being *102 pounds* It wa large, soft, and yellow To the naked eye the was no appearance of cirrhosis It was thickly studde throughout with dead white specks, the large having the size of a pin's head, and the could be seen to be surrounded by a zone hyperæmia. There was no iron reactio Microscopical examination showed no tra of cirrhosis or leucocytal infiltration Th whole organ was degenerate, the cells bein cloudy and largely pigmented and the nucl staining badly or remaining *invisible* Th white specks consisted of necrosed liver cell numerous irregularly shaped nuclei showing u among the granular structureless débris, an they were teeming with bacteria, mostly ro resembling the bacillus coli

The spleen weighed 25 ounces It was larg and rather soft. The capsule was slightly thic ened. Section revealed a large white infar and the cut surface showed numerous whi specks similar to those in the liver Micr scopically there were seen to be a slight fibros affecting the trabeculæ and sheaths of th vessels and considerable evidence of endotheli proliferation The white specks proved to b patches of focal necrosis similar to those in th liver There was no obvious change in th Malpighian bodies. The kidneys were large soft, and yellow, the cells being cloudy or ver granular The pancreas showed no change an there was no apparent alteration in an lymphatic glands. The marrow was no *examined*

The heart was pale, with large subpericardia hæmorrhagic blotches and numerous petechi in its muscle There was an early stage o pericarditis, and both mitral and aortic valve showed distinct vegetations of recent origin The lungs showed some broncho pneumonia i *the lower lobes, and here also*, as in th heart, the serous surface showed early inflam mation with deposit of lymph The stomac and small intestine showed no change an there was no sign of ankylostoma or othe worm The cæcum and adjoining portion of the colon for a total length of eight inches presented *the very peculiar appearance seen* in the illustration. The normal folds were greatly swollen in height and in breadth, and being separated only by slight sulci they bore some resemblance to the convolutions of the brain The thickening is shown by the fact that in places the distance from the peritoneal coat to the summit of a fold in a section through the bowel wall amounted to more than half an inch. The tissue was exceedingly firm, so that felt from the outside it suggested a new growth As seen from the inside the whole patch was dark grey or black. *In the* transverse and descending colon were two patches of croupous inflammation, each being covered by a dirty white membrane consisting of necrosed mucosa and coagulated exudation.

Microscopical examination of the affected part of the cæcum showed that the changes comprised hæmorrhage, inflammatory exudation, necrosis, and bacterial invasion. To demonstrate the early stage of the lesion an outlying flat-topped sessile projection of the mucous membrane may be taken. From such a spot the whole of the epithelium has been shed including the cells lining the glands, though traces of the latter remain. In the underlying submucosa there is some exudation of small round cells and the remains of the mucosa are in a condition of early necrosis Immediately under the muscularis mucosæ, which is itself altered by the necrotic process to such an extent as not to be recognisable in the central region of the elevation, hæmorrhage has taken place into the submucosa. The muscular tissue, though swollen, is comparatively little affected One section, which contains the edge of a lymphatic follicle, shows that the follicle has not participated in the change no necrosis and no infiltration with polymorphonuclear cells having occurred.



Cæcum in acute splenic anæmia

In a section through the most advanced part of the disease it is seen that the mucosa is swollen and necrotic over large areas, the submucosa is distended with inflammatory exudate now undergoing necrotic change, while hæmorrhages and distended vessels are present in the subjacent parts of the inner circular layer of muscle Throughout the thickness of the necrotic mucosa, but most abundant in its deeper part, are numerous circular or oval areas of finely granular material, which appear to be the remains of the fundi of glands crammed with disorganised or dead epithelial lining Bacilli and cocci are abundant in the necrotic mucosa and they extend also into the deeper layers, though here they seem for the most part to be limited to vessels, definite connective-tissue spaces or lymphatics. The masses of hæmorrhage and exudate in the deeper submucosa and inner muscular layer do not seem to be infected.

Remarks —A splenic anæmia—i.e. an anæmia of secondary type associated with enlargement of the spleen—stands out

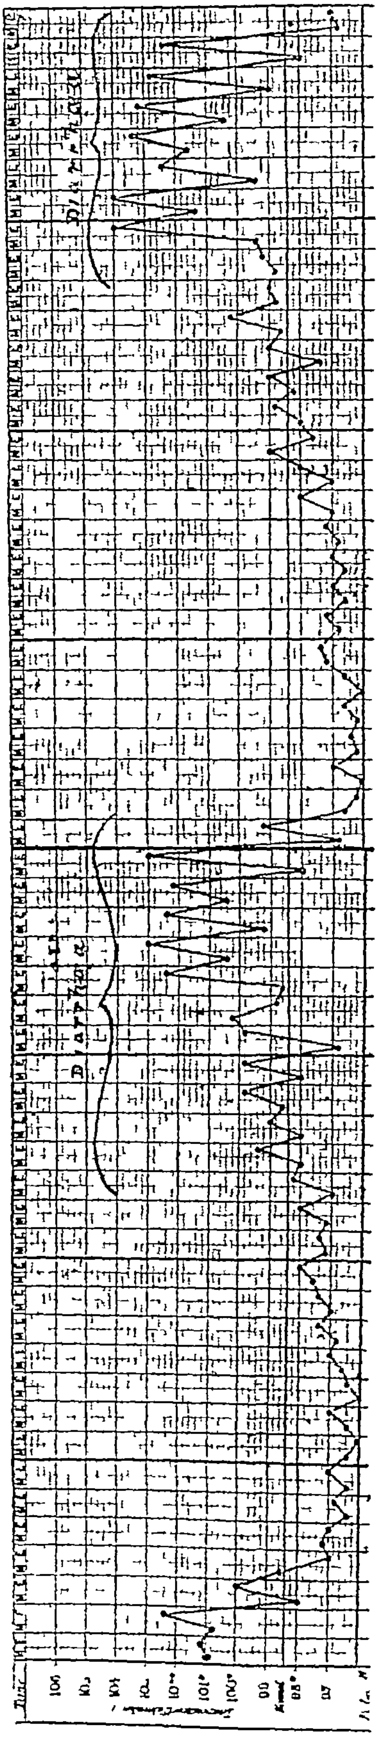


CHART 2

as a distinct symptom group It is as definite as pernicious anæmia and leukæmia, and though less common than these it is probably far more common than the scarcity of recorded instances would suggest. It consists of a primary splenomegaly, with more or less profound anæmia of a secondary type, without the characteristic blood changes of pernicious anæmia, without any material alteration, quantitative or qualitative, of the leucocytes (though leucopenia is generally noted), without enlargement of glands, generally showing pyrexia at some period, and in a late stage associated with some fibrosis both of the spleen and of the liver In many cases coming under this definition the duration is measured in years, and it is to these cases that Osler[1] has particularly directed attention A duration of 15 years has been noted. It is in such long standing cases that hæmatemesis and ascites are apt to occur, leading perhaps to an erroneous diagnosis of cirrhosis of the liver In a smaller number of cases, however, death occurs in from three to twelve months Thus two forms—an acute and a chronic—may be recognised. It is possible that when the actual cause is discovered these two forms will be found to be distinct But the symptoms and state in the two forms are identical, except in the occurrence of repeated hæmatemesis in the chronic form And at present there seems to be little reason for arbitrarily separating them and for considering them as different diseases merely on the score of a difference in duration

In the example of the acute form here recorded, the size of the spleen and the character of the blood exclude a diagnosis of pernicious anæmia The blood state points rather to defective formation than to increased hæmolysis. At the same time the latter process is indicated, in spite of the absence of iron reaction in the liver, by the character of the urine and the yellow tint of the skin. The chief points of interest are (1) the apparent onset of the disease after pneumonia, (2) the curious periodicity of the fever as shown in the temperature chart (Chart 2), which might almost be taken as a copy of the chart given by West[2], (3) the steady improvement under treatment as shown in the blood chart, and (4) the cutting short of this improvement by the supervention of a general infective state, as shown by necrosis of the bowel wall focal necrosis of the liver and spleen, pericarditis, pleurisy, and acute endocarditis

As regards the nature of splenic anæmia a string of facts points strongly to the localisation of the cause in the spleen 1. In the first place it is highly probable that the enlargement of the spleen is practically the first sign of disease In the case of a man, aged 64 years, recently in St. Thomas's Hospital, who had never had any illness except influenza and had led a perfectly healthy life, the onset of an acute splenic anæmia was very clearly described. In December, 1900, he began to notice a little unusual tiredness after his day's work and some disinclination for exertion. But he was little incommoded by this and did not think it worth while to consult a medical man until the end of January, 1901—i.e., not more than two months later The spleen was then found to be already greatly enlarged, the lower end being at the level of the umbilicus As regards the state of his blood (anæmia of secondary type) and his other symptoms he departed in no important particular from the case above described and he died six months after the beginning of symptoms with a spleen weighing 30 ounces When he went into hospital he was very ill and the time for splenectomy had gone by 2 In the second place it is certain that removal of the spleen will effect a cure and that it is the right course to pursue if it is estimated that the patient can survive the operation itself Sippy[3] and Harris and Herzog[4] give a list of 19 cases of primary splenomegaly in which *splenectomy was performed* Of these 14 patients recovered and four died, of one the result is not stated 3 Further there is evidence to show that in long standing cases at any rate the changes in the spleen have a somewhat distinctive character in the marked endothelial proliferation.

It is possible that this endothelial change is itself responsible for the blood state, as has been suggested, by the production of a hæmolysing enzyme, wholly abnormal or an exaggeration of a normal product. But such a theory, however plausible, is incomplete, as it still leaves us without a cause for endothelial change and the tendency must be to fall back on the hypothesis of the existence in the spleen of a long lived bacterial or parasitic agent. At any rate, on any view it is difficult to get away from the idea that the actual cause of the disease resides in the spleen. The established disease bears a close resemblance to the state of chronic malarial cachexia with permanent enlargement of the spleen

As regards the case here described, the question presents itself as to whether the infective termination can be allowed to have any bearing on the causation of the disease On finding the very remarkable condition in the cæcum above described one was tempted at first from the hardness and blackness of the part and the presumable chronicity of the change to imagine the possibility that this might prove to be a primary lesion, from which the blood state had arisen But the microscopical examination shows that it was not of long standing and it must be interpreted as a recent necrosis of the bowel wall, consequent on, or followed by, hæmorrhage into its tissue, with secondary bacterial invasion Though it is a much rarer change, it must be regarded as being essentially of the same nature as the patches of croupous inflammation which occurred in another part of the colon, both of them meaning loss of tissue vitality and secondary bacterial infection Neither change can be allowed to have direct bearing on the question of the bacterial or non bacterial origin of splenic anæmia At the same time it may be noted that a terminal croupous inflammation of the bowel, though it does occur in non bacterial diseases such as cirrhosis and renal disease, is far more common in bacterial conditions such as pyæmia septicæmia, and pneumonia.

As regards the state of general infection which was the immediate cause of death, its bearing on the question of the bacterial origin of splenic anæmia is vitiated by the occurrence of the intestinal necrosis. The whole series of changes, the focal necrosis of the liver and spleen, the pleurisy and pericarditis, and the acute endocarditis, may well have been the result of the intestinal infection But their occurrence seemed to be worthy of record in connexion with a disease of which so little is known As to the focal necrosis of the liver and spleen we know nothing of such a state except as arising from the action of bacterial toxins. In man it is confined to typhoid fever and dysentery In the former disease an instance is described and depicted by Glynn[5] The finding of recent vegetations on the valves after death from any acute febrile disease is a strong indication that that disease has been of an infective nature. Examples may be drawn from scarlet fever and, perhaps, other specific fevers, from pyæmia, erysipelas, and septic diseases generally, and from pneumonia. Considering the presence of the intestinal lesion, however, there seems to be no justification for laying stress on the endocarditis in this case as having a bearing on the origin of splenic anæmia. But, at the same time, it may be noted that a similar acute terminal endocarditis has been recorded in three cases of splenic anæmia by West,[6] Williamson, and Strümpell, and out of six cases of febrile (infectious) purpura occurring under the care of one of us similar early vegetations were found in three cases on the valves of the heart

THE HEIGHT OF THE DIAPHRAGM IN RELATION TO THE POSITION OF CERTAIN ABDOMINAL VISCERA

BY CHARLES T ANDREW, M B, CH B, B SC ABERD,
JUNIOR DEMONSTRATOR OF ANATOMY, ABERDEEN UNIVERSITY

WITHIN the last few years attention has often been drawn to abnormalities in the shape and position of certain of the abdominal viscera, especially with reference to the part these play in the causation of disease. Some short time ago a pamphlet was published by Dr Arthur Keith on the "Anatomy of Glénard's Disease" and lately his Hunterian Lectures on this subject,[1] in which he laid stress on the action of the diaphragm and thinning of the abdominal walls as being important factors in the etiology of the condition. Since the introduction of the formalin method of hardening the abdomen one is often struck with the great variations in the position of such viscera as the stomach, liver, and gall bladder, and it is observed that these occur mostly in female subjects.

[1] THE LANCET March 7th (p 631) and 14th (p 709), 1903

The following observations were made with a view to ascertain the height of the diaphragm in the two sexes and to find out if there was any relation between the height of the dome, the position of the viscera, and the thickness of the abdominal wall, a guide to the latter being obtained by estimating the average thickness of the rectus muscle on the right side midway between the umbilicus and pubes. Nine consecutive cases in the dissecting room were examined without being selected in any way and the notes made will be found in the accompanying table.

CASE 1.—The patient was an old female. A marked Riedel's lobe was present, the right lobe of the liver reaching to a quarter of an inch above the highest point of the crest of the ilium. The gall bladder was greatly dilated and filled with gall stones and communicated with a large abscess cavity in the right lobe of the liver. Matted adhesions were present between the under surface of the liver, transverse colon, and first and second stages of the duodenum. The abscess cavity measured five and a half inches long, four and three-quarter inches broad, and opened into the first stage of the duodenum by a narrow channel admitting a glass rod. The thickness of the rectus muscle in this case was very small, measuring three millimetres.

CASE 2.—The patient was an old male. The liver was greatly displaced backwards on the diaphragm. The anterior border in the mesial line was opposite the junction of the sixth costal cartilage with the sternum; in the right mammary line at the lower border of the sixth costal cartilage; and in the right mid axillary line at the lower border of the eleventh rib. The gall bladder was pressed against the under surface of the right lobe of the liver and was situated deep opposite the eighth right rib in the anterior axillary line. The under surface of the right lobe was greatly indented by the hepatic flexure of the colon. No gall stones were present. The transverse colon crossed the abdomen six and a quarter inches below the tip of the xiphoid cartilage. A greatly loaded colon evidently accounted for the displacement of the liver. The thickness of the rectus muscle was eight millimetres.

CASE 4.—The patient was a female. The right lobe of the liver covered the right kidney to within half an inch of the lower pole, showing an indistinct Riedel's lobe. The gall bladder was placed one inch below the tip of the ninth right costal cartilage. No gall stones were present. The great curvature of the stomach was placed six and a quarter inches below the tip of the xiphoid cartilage. The transverse colon appeared low down one and a quarter inches above the symphysis pubis. The thickness of the rectus muscle was four millimetres.

CASE 5.—The patient was a female. A marked Riedel's lobe was present, the tip of the right lobe of the liver reaching to the highest point of the crest of the ilium. The gall-bladder was greatly dilated, the fundus measuring seven and a quarter inches long and two and a half inches broad. It lay in a fossa the upper half of which was bounded by the right lobe of the liver and the anterior surface of the right kidney, and the lower half, partly in the right iliac fossa, by the hepatic flexure of the colon which did not extend above a line drawn from the left anterior spine to the umbilicus. A few gall-stones were present. In this case the gall bladder was placed almost exactly in the position of the normal appendix. The cæcum lay deep in

TABLE GIVING PARTICULARS OF THE HEIGHT OF THE DIAPHRAGM IN RELATION TO THE POSITION OF CERTAIN ABDOMINAL VISCERA IN NINE CASES.

No.	Sex.	Height of diaphragm right mammary line.	Height of diaphragm left mammary line.	Liver below the costal margin.	Stomach below the costal margin.	Transverse colon below the costal margin.	Gall bladder.	Reidel's lobe.	Average thickness of the recti.
1	F.	Fifth rib.	Fifth interspace.	Three inches below the tip of the ninth costal cartilage.	—	—	Large abscess cavity continuous with abscess in the liver gall stones.	Present.	3·0 mm.
2	M.		Fifth rib.	Greatly displaced back on the diaphragm.	—	Six and a quarter inches below the tip of the xiphoid cartilage.	Eighth rib in anterior axillary line.	Absent.	8·0 mm.
3	M.	Fourth interspace.	Fourth rib.	Three inches below the costal margin.	One and a half inches below the tip of the xiphoid cartilage.	Two and a quarter inches below the tip of the xiphoid cartilage.	—		7·9 mm.
	F.	Fifth rib.	Fifth rib.	—	Six and a quarter inches below the tip of the xiphoid cartilage.	One and a quarter inches above the pubes.	One inch below the tip of the ninth costal cartilage.	?Present. Right lobe half an inch below the lower pole of the kidney.	4·0 mm.
5	F.	Fourth rib.	Fourth rib.	Costal margin.	—	—	Partly in the iliac fossa greatly dilated. 7¼ inches by 2½ inches gall-stones.	Present.	2·0 mm.
6	F.	Fifth rib.	Fifth interspace.	—	Diverticulum of the cardiac end in a pouch of the diaphragm.	—	—	Absent.	—
7	F.	Fourth rib.		—	Five and three-quarter inches below the tip of the xiphoid cartilage.	Seven inches below the tip of the xiphoid cartilage.	Immediately below the costal margin at the tenth costal cartilage.	„	—
8	F.	Sixth interspace.	Sixth rib.	Four and three-quarter inches below the tip of the xiphoid cartilage.	Seven inches below the tip of the xiphoid cartilage.	Two inches above the pubes.	—	Not distinct. Tip of the right lobe reached the lower pole of kidney.	[illegible]·0 mm.
9	F.	Sixth rib.		Two and a half inches below the tip of the xiphoid cartilage.	Five inches below the tip of the xiphoid cartilage.	Seven inches below the tip of the xiphoid cartilage.	One and a quarter inches below the tip of the ninth costal cartilage.	Absent.	3·0 mm.

the right side of the pelvis, the appendix, four inches long, lying in the pouch of Douglas The thickness of the rectus muscle was in this case two millimetres.

CASE 6 —The patient was a female. In this subject the stomach showed a curious diverticulum at the cardiac orifice Placed immediately to the left of the œsophageal opening there was seen a dome shaped pouch of the diaphragm into which a finger could easily be passed, and drawn up into this was part of the cardiac end of the stomach, measuring vertically about one inch (see Fig 1) The diverticulum could easily be pulled down from this pocket when it was noticed that the part of the stomach wall which lay against the neck of the pouch was thickened The peritoneum was reflected from the diaphragm to the stomach at the top of the pouch On slitting open the viscus the circular fibres of the œsophagus were seen to end at the right of the pouch So that it was without doubt a case of diverticulum of the stomach and not, as was thought at first, a dilatation of the lower end of the œsophagus The walls of the stomach were not thinned in any way, but the mucous membrane was thrown into well marked rugæ. The pylorus felt on examination very hard and thick as if some sort of stricture was present and the orifice would scarcely admit a glass rod, but microscopic examination showed no definite hypertrophy As there was no evidence of dilatation of the stomach, this apparent stenosis was evidently artificial and perhaps due to the hardening effect of formalin.

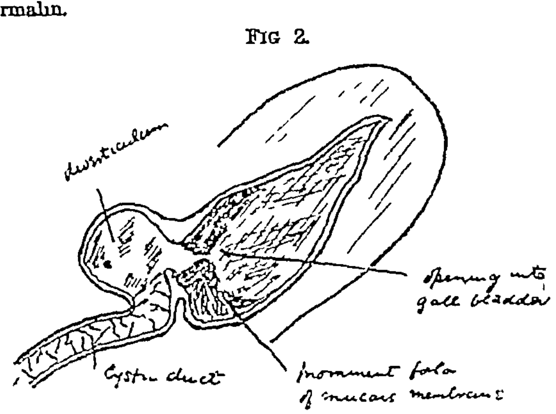
FIG 2.



Illustrates gall bladder with a diverticulum of the cystic duct

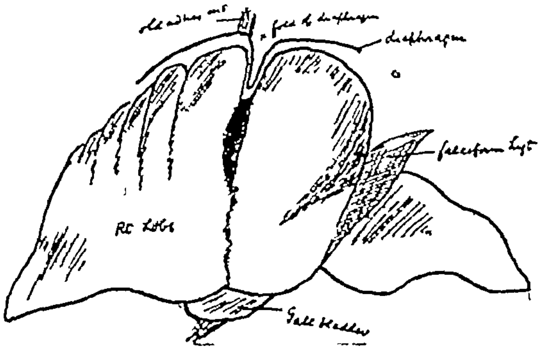
CASE 8.—The patient was a female. In this case the viscera appeared to be situated at a much lower level than usual. In the mesial line the liver extended to four and three-quarter inches below the tip of the xiphoid cartilage Although no distinct Riedel's lobe was present the tip of the right lobe of the liver reached as far as the lower pole of the right kidney The gall bladder was situated one and three quarter inches below the tenth right costal cartilage and the transverse colon two inches above the symphysis pubis. The thickness of the rectus muscle was four millimetres

The following two cases are interesting as exhibiting abnormalities in the liver and gall bladder in two female subjects

The first showed a well marked diverticulum of the cystic duct. The duct formed a sharp bend and opened at rather an acute angle into the diverticulum, which communicated with the gall bladder by a narrow circular orifice bounded by prominent folds of mucous membrane A few old adhesions were attached to the diverticulum

The second was a case of compressed liver taken from an old female subject. The liver measured seven inches from side to side and four inches high One and a half inches to the right of the longitudinal fissure was a deep grooving of the convex surface of the right lobe and in this lay a diverticulum of the diaphragm To the right of this were five other indistinct furrows A few old adhesions were attached to the right of the dipping in of the diaphragm and also to the fundus of the gall bladder (see Fig 3)

FIG 3



Liver in old female subject showing a fold of diaphragm dipping into the liver

On looking at the syllabus of the nine consecutive cases examined the first thing which strikes one is, I think, the great variation which seems to exist in the height of the diaphragm and the fact that this variation is well marked in the female subjects. In the seven females the height of the dome in the right mammary line varied from the fourth rib to the sixth interspace, whereas in the two males it did not extend lower down than the fifth rib Secondly, it is remarkable that so many abnormalities in the position of the viscera should have existed in such a small number of subjects and that these should have existed chiefly in females, for in the seven cases examined there were two distinct and two indistinct cases of Riedel's lobe of the liver, two cases of gall stones and two affections of the gall bladder, and one abnormality of the stomach Both cases of Riedel's lobe were accompanied by gall stones and in one of the cases there was an abscess in the liver and gall bladder, while in the other the gall bladder was greatly dilated and lay partly in the iliac fossa. Again, the measurements of the recti muscles as an indication of the strength of the abdominal muscles are interesting, as in every case they are much smaller in the females than in the males The thickness is especially diminished in the two cases in which a Riedel's lobe is present, the recti in these cases being so thin as to feel almost like a piece of brown paper The distance of the great curvature of the stomach and the transverse colon below the xiphoid cartilage was also greater in the females than in the males. In the case in which the diaphragm reached the sixth interspace the great curvature was seven inches below the xiphoid cartilage and the transverse colon was two inches above the pubes

QUEEN'S HOSPITAL, BIRMINGHAM —This hospital ministers to the wants of a district containing a population of at least 700,000 persons The in patients treated last year amounted to 2065 the out-patients to 28,947. The yearly expenditure is over £11,000

ANGINA PECTORIS A CRITICISM AND A HYPOTHESIS

BY E. H COLBECK, M D CANTAB., M.R.C P LOND,
PHYSICIAN TO OUT PATIENTS AT THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST PHYSICIAN TO THE METROPOLITAN DISPENSARY

THE field of cardiac pathology still resounds with the clash of conflicting arguments and the fray has nowhere been more hotly contested than over angina pectoris. Yet, in spite of the 61 attempts which according to Huchard, have been made to elucidate this symptom group or syndrome, as it is now the fashion to call it, the precise method of its causation remains more or less a mystery It will be the object of this paper to criticise the more important theories which have been advanced and also to submit a hypothesis whereby the mode of production of this curious and interesting group of symptoms is capable of explanation.

It is necessary, in view of the conflicting opinions held by clinicians with respect to the set or group of symptoms comprised under the term angina pectoris, to define clearly the nomenclature that will be adopted. If, as Professor T Clifford Allbutt pertinently observes, the title angina pectoris be used to include a variety of symptom groups which, though they may present a superficial clinical resemblance in the manifestation of some form of cardiac perturbation, yet differ widely and fundamentally in their etiological and pathological relations, all definite use of names comes to an end. In this connexion, too, it may be pointed out that the use of such terms as "false" angina pectoris and "pseudo" angina pectoris is altogether objectionable and fallacious inasmuch as it is obviously incorrect and unscientific to call a disease or group of symptoms by what it is not, rather than by what it is For the profitable discussion of any scientific problem it is well to deal so far as possible with clear-cut and definite conceptions and with this object in view the group of symptoms included under angina pectoris will now be clearly defined

The earliest and central feature of the paroxysm is pain, heart-rending, insistent, well nigh insupportable pain, which though initially and mainly retro-sternal tends to radiate over the upper portion of the thorax and down one or both arms as far as the elbows or wrists, and sometimes as far as the fingers. A sense or apprehension of impending death is the more or less constant and dread accompaniment of the pain. Agonised by this two-edged weapon the sufferer is rendered powerless and incapable of the slightest movement, he remains, as it were petrified and rooted to the spot. The apprehension of sudden death is in the large majority of cases realised sooner or later and post-mortem examination commonly reveals aortic and coronary atheroma associated, it may be, with a greater or less degree of myocardial degeneration

Such then in outline is the clinical picture of angina pectoris, the picture drawn so forcibly and accurately by Heberden in the year 1768. Other so-called anginas are but mimicries of this terrible and deadly syndrome and in order to put an end to the misnomer and consequent nosological confusion involved in the use of the terms "false angina pectoris, 'pseudo" angina pectoris, and the like, I would suggest that the name angina cordis be applied to these allied but widely different cardiac perturbations. The term angina cordis, moreover expresses more or less exactly the condition of the heart in these attacks and it can be suitably qualified in accordance with its mode of origin, as for instance, angina cordis vasomotoria, angina cordis toxicata, &c

The association of angina pectoris with disease of the coronary arteries and myocardium was observed and insisted upon by Jenner and is now generally admitted The relation between these coronary and myocardial changes and the symptoms of angina pectoris has long been the subject of speculation but it may safely be asserted that none of the theories hitherto advanced has afforded a perfectly satisfactory explanation. The theory of intermittent claudication' which, according to Osler, was originally advocated by Allan Burns, has been employed in the interpretation of the connexion between the coronary affection and the symptoms of angina pectoris. This interesting morbid condition is observed in the horse and occasionally in man and depends on arterial thrombosis or embolism whereby a large muscular territory, usually one or both limbs, is suddenly deprived of blood and becomes temporarily paralysed. The muscular paresis is apparently attended by great suffering and it is suggested that the pain and presumably the other phenomena of the anginal paroxysm are, in like manner, dependent on coronary ischæmia. It is, however, doubtful whether coronary thrombosis in man gives rise to pain and apart from this objection recurrent and frequently repeated attacks of angina which may occur without any appreciable disturbance or alteration in the action of the heart could not possibly be due to intermittent claudication.

The symptoms of angina pectoris and more particularly the pain that is so prominent and characteristic a feature of the paroxysm have been ascribed by many distinguished authors to cramp of the cardiac muscle The most extraordinary divergence of opinion appears with respect to this theory. Many eminent authorities deny that the cardiac muscle is capable of cramp, while other equally illustrious writers assert that this kind of painful muscular contraction can, and does, occur From a physiological standpoint, however, there is no evidence that the heart is capable of the cramp-like contraction that is observed in skeletal muscles And if the possibility of cramp of the heart be admitted its occurrence even when localised would surely interfere with the orderly and uniform performance of the cardiac systole and in this way lead to much greater disturbance of the action of the heart and of the rhythm and character of the pulse than is commonly found to be the case. Furthermore, cramp of the heart does not account for the angor animi or sense of impending death which is a characteristic feature of the anginal attack. Why, too, does not cramp occur in connexion with disease of the right ventricle? Why, too if cramp be concerned in the production of the symptoms of angina pectoris should the pain be relieved by the establishment of mitral regurgitation? Why, since the conditions which presumably favour the occurrence of cramp are not infrequently fulfilled should the phenomenon be so rarely observed? Why should cramp so rarely affect the heart of the class of patients who come to hospitals? It is necessary to obtain a satisfactory reply to these questions before cramp of the heart be admitted as the cause of angina pectoris

Current theories of angina pectoris link together cramp and paralysis of the cardiac muscle. But is not this blowing hot and cold with the same breath, are not these conditions the antithesis of each other and mutually destructive from a causal point of view? Be this as it may the objections urged above to the agency of cramp apply equally forcibly to the operation of paralysis of the cardiac muscle as a cause of the anginal attack Distension of the heart and stretching of the nerve elements in the cardiac wall cannot be a cause of the phenomena of angina if associated with increased arterial pressure since the two conditions are impossible at the same time Moreover, dilatation and stretching of the cardiac walls are frequently observed and are not attended by the symptoms of angina pectoris

The phenomena of the anginal attack have been attributed by a large number of eminent authorities to neuralgia or neuritis of the cardiac nerves. The objections to this theory are that inflammatory and degenerative conditions of the cardiac nerves have frequently been observed without any of the symptoms of angina pectoris Again, in those cases of angina in which nerve changes have been found there have also been observed well marked aortic and coronary atheroma, with or without myocardial degeneration. Neuralgia and neuritis of the cardiac nerves have also been found in association with symptoms which do not resemble those of angina pectoris. The mode of onset of the anginal paroxysm and the rarity of its occurrence among women are features opposed to the purely nervous theory of its mode of production Moreover, the angor animi is not explained by the theory under examination, nor does neuralgia of the cardiac nerves afford a satisfactory interpretation of the almost invariably fatal termination of angina pectoris.

Professor Clifford Allbutt is of the opinion that the pain of angina pectoris arises in the aorta and in cases of chronic disease of this vessel, at all events, is due to tension and stretching of the degenerated aortic walls. I cannot help thinking that for so able and brilliant a pleader Professor Allbutt's advocacy of this theory is somewhat half hearted.

The hypothesis in question does not permit the coronary and myocardial disease any causal influence in the production of the anginal attack. It is to be observed, however that these changes in relation to the aortic disease are advantageous and conservative inasmuch as they make for lessened aortic blood pressure and therefore diminished aortic stress A high blood pressure in the aorta of protracted duration is common enough without the incidence of anginal symptoms, Moreover, those occupations which are prone to give rise to aortic strain and stress do not furnish any large proportion of the cases of angina pectoris—indeed, angina pectoris is rarely observed among blacksmiths, labourers, navvies, porters, and the like Nor, so far as I am aware, does this hypothesis attempt to explain the sense of impending death which, as I have already insisted, is one of the central features of the anginal seizure. It seems to me that Professor Allbutt is much nearer the mark when he suggests that in addition to the static changes which are found there is a dynamical factor in the causation of this symptom group

The vaso-motor phenomena that are observed in connexion with angina pectoris will be considered later A hypothesis which aspires to elucidate the mode of production of the symptoms of angina pectoris must account not only for the dolor pectoris but also for the angor animi. It must likewise afford a satisfactory interpretation of the character of the pulse and of the vaso motor phenomena associated with the paroxysm The various theories which have been under review fail to satisfy fully these requirements and herein lies the justification, if one be needed, for yet another attempt to explain the mode of production of this remarkable and enigmatical syndrome. It is now generally allowed that disease of the coronary arteries and of the myocardium is in some way associated causally with the incidence of angina pectoris The coronary atheroma, which is the morbid condition usually found, and the myocardial degeneration are unequally distributed over the wall of the heart. Furthermore, careful microscopical examination usually reveals a greater degree and extent of myocardial disease than the macroscopical appearances indicate It is probable, too, that the nervous tissue—i.e , ganglia and nerve fibres—distributed over the wall of the heart suffers in common with the muscular substance of the organ and tends therefore to undergo similar degenerative changes. I would again insist on the fact that in both cases the morbid changes have a "patchy" irregular disposition

So long as the heart is acting quietly the areas of degenerated muscular tissue are able, even with a relatively insufficient blood supply, to take their share in resisting and overcoming the intra cardiac pressure during systole. So soon, however, as the work of the heart is increased as, for instance, by exertion, emotion, &c., the area or areas of degenerated muscular wall are at a double disadvantage, inasmuch as the diseased and partially occluded coronary vessels are unable to satisfy the increased demand for blood to the territories or patches of deteriorated muscular tissue. The areas of degenerated ventricular wall are thus unable to take their proper share in resisting the increased intra cardiac pressure and in consequence undergo more or less distension and stretching Herein lies the explanation of the pain experienced during the anginal seizure, since the affected portions of the ventricular wall contain nervous tissue in an unduly impressionable and irritable condition, which must be subjected to a considerable degree of stretching and tension In other words, the hypothesis I suggest ascribes the pain experienced in the anginal paroxysm to localised distension and stretching of the ventricular wall. If this hypothesis be well founded it must also satisfy the requirements that were detailed when the question of cramp of the cardiac muscle was discussed and I think this will on examination be found to be the case.

The hypothesis does not entail any interference with the regular and uniform performance of the ventricular systole , the wave of contraction passes uninterruptedly from apex to base, but over certain portions of the ventricular wall it is qualitatively and quantitatively deficient In these conditions the action of the heart and the rhythm and character of the pulse may remain, so far as physical examination is concerned, undisturbed and unaltered, and in the majority of anginal seizures this state of affairs obtains It is conceivable, however that should the area or areas of degenerated ventricular wall exceed a certain proportion in relation to the amount of sound muscular tissue the heart might falter, the pulse become irregular, and the blood pressure fall. This sequence of events has also been observed, more especially in old standing cases and in the terminal stages of frequently repeated anginal attacks

The establishment of mitral regurgitation in the course of angina pectoris relieves the intra ventricular pressure and in this way diminishes the stress on the cardiac wall, and hence the degree of distension and stretching of the diseased muscular territories Nitrites and other vaso dilators owe their beneficial influence to a similar mode of action—viz., the reduction of intra ventricular pressure. The safety valve action at the tricuspid opening effectually precludes the operation of the conditions which might otherwise give rise to undue stress on the wall of the right ventricle and it is for this reason, I take it, that anginal phenomena are rarely if ever associated with disease on this side of the heart Again, the hypothesis which I suggest provides a feasible and attractive explanation of the angor animi which is usually more or less neglected in the current theories of the pathogenesis of angina pectoris It is obvious that if distension and stretching of localised areas of the cardiac wall take place during systole the ventricular parietes are *simultaneously* undergoing contraction and expansion. The effect of this dynamical perversion of the cardiac movements on the impressions transmitted to the cardiac centre during the ventricular contraction must be contradictory and antagonistic, and the intensity of the opposed efferent impulses will be influenced by the relative amounts of sound and degenerated muscular tissue and also by the degree of extra work demanded of the heart. The cardiac centre must in these circumstances be thrown into a turmoil, and it is hardly a matter for surprise that a threatened disorganisation of the very citadel of life should occasion the sensation of impending death. Moreover, the perturbation of the cardiac centre spreads, no doubt, to adjacent centres and herein lies the explanation of the vaso-motor phenomena as well as of the nausea, vomiting, flatulence, hiccough, and so forth which so commonly accompany the anginal paroxysm.

A few subsidiary and contingent conditions still remain for consideration. The extraordinary variability in the incidence of anginal attacks is explicable on the assumption that the coronary and myocardial affection does not always provide the exact conditions for the production of localised stress on the ventricular wall. Indeed, it is not unreasonable to surmise in the light of the present hypothesis that the production of an anginal seizure in coronary and myocardial disease is always more or less of an accident. Clinical observations appear to bear out this supposition The occurrence of sudden death can be explained in two ways. Thus the sudden arrival at the cardiac centre of equally balanced antagonistic impulses might inhibit the action of the centre, or that portion of the ventricular wall which is known as Kronecker's centre in the dog and is situated in the lower portion of the upper third of the inter ventricular septum may be the seat of disease (coronary or parietal) and hence of distension and stretching in the manner previously indicated so that sudden death may be due either to a reflex or to a local cause.

The remarkable immunity from anginal symptoms that is displayed by the class of people who seek advice and treatment at hospitals is, I imagine, due to the fact that the conditions of life in which these patients live lead to more general and extensive myocardial degeneration and hence to more readily produced failure of the heart than is the case with the more well to-do members of the community Angina sine dolore is explained on the assumption that the deterioration of the nervous elements in the cardiac wall becomes so great that they fail to react to stimuli which ordinarily give rise to the sensation of pain. It is extremely interesting to observe that, under the operation of the causal factors I suggest, the incidence of this form of angina pectoris justifies a serious prognosis, since it implies grave deterioration of the wall of the heart

The relation between "pseudo" angina pectoris, or angina cordis vasomotoria as I prefer to call it, and angina pectoris still remains to be discussed. In angina cordis vasomotoria the essential feature of the paroxysm is, as Solis Cohen has pointed out, a vaso-motor ataxia, whereby the heart is suddenly exposed to stress which, after a period of stormy nervous action, subsides and enables the organ again to obtain control of the circulation The cardiac embarrassment, in these conditions, is due to sudden and general arterial constriction, which in turn depends on the operation of imperfectly controlled central and peripheral stimuli on unstable and unduly sensitive vaso-motor and nervous centres.

In angina pectoris, on the other hand, although the general arterial blood pressure is probably always above the normal, the vaso-motor phenomena are, in part at least, secondary and not primary features of the attack It is possible, indeed not improbable, that spasm of the coronary arteries (which are affected in common with the rest of the arterial system) plays a similar but subordinate rôle in the production of cardiac pain in angina cordis vasomotoria to that which organic disease of these vessels does in the causation of an attack of angina pectoris. Moreover, it is conceivable that long-continued and frequently repeated attacks of angina cordis from any cause might ultimately lead to disease of the coronary arteries and myocardium and in this way the various forms of angina may merge imperceptibly into one another From this point of view then, the existing antagonism may be resolved into a harmonious whole by means of which the incidence of cardiac angina is freed from the difficulties which have hitherto beset the solution of its occurrence and mode of production.

Upper Berkeley-street W

A CLIMATOLOGICAL ASPECT OF THE NAUHEIM TREATMENT OF DISEASES OF THE HEART

By LESLIE C THORNE THORNE M.D , B Sc Durh ,
MEDICAL EXAMINER TO THE TECHNICAL EDUCATION BOARD OF THE LONDON COUNTY COUNCIL.

It is now many years since the Nauheim treatment of diseases of the heart was first practised in England, and those who have devoted special attention to the subject have had time to observe the effects of the English climate upon it and have been able so to regulate its application as to produce the best results obtainable, these results being in many cases of a highly satisfactory nature. There are still, however, a large number of medical men who either do not use this method of treatment at all or do not give it that place of importance as a therapeutic agent which it rightly deserves. The reason for this, I believe, lies in the fact that the Nauheim treatment when administered in England has in some ways to be modified and adapted to the climate, whereas many medical men who have given it what they believe to be a fair trial have prescribed the comparatively long and frequent baths and the frequent resistance exercises that often produce good results at Nauheim, but, according to my experience in London, only benefit a small minority of mild cases of heart disease and do definite harm to the more serious cases.

As I am convinced that many who have hitherto found this treatment of little use in England would be led to regard it as a really valuable therapeutic agent were they to adopt the methods of administration that I have found most successful in London, I do not hesitate to give a short sketch of a course as I have carried it out for some years with very satisfactory results especially in cases which have not been greatly benefited by rest, the administration of drugs, or other methods of treatment In giving this sketch I shall endeavour to mention all the really important points to be attended to so that any medical man who has not hitherto administered the Nauheim treatment may be able to do so by carefully carrying out the directions given.

The administration of the baths—Taking for example, a case of dilated irritable heart, a sequel of influenza, causing symptoms of vertigo palpitation dyspnœa, insomnia, cardiac pain, lassitude, and general invalidism, I begin by giving a three or four minutes bath at a temperature of 97° or 98° F , containing from four to five pounds of Droitwich salt and from five to six ounces of calcium chloride The pulse is carefully noted before, during and after the bath and the result aimed at, and usually obtained, is a diminution in frequency, an increase in volume, and a lowering of tension. The patient goes to bed for one hour after the bath and is not allowed during this time to read write or talk. A bath of similar strength temperature, and duration is given the following day On the third day the Schott exercises are usually given instead of a bath, the patient resting for a minute or so between each exercise and lying down for half an hour after them.

Frequency of baths.—The baths are given on two consecutive days and the exercises on the third day for the first week or fortnight, according to the severity of the case and the result produced upon the heart's action. After the first week or fortnight baths are given three days in succession with an interval for exercises on the fourth day In my opinion it is a mistake to give baths for more than three days in succession even towards the end of the course

Strength of baths—If the patient does well and the circulatory system reacts well I increase the strength of the baths by one pound of sodium chloride and one ounce of calcium chloride every second bath up to the tenth or twelfth To the tenth or twelfth bath I add half of one of Sandow's effervescing packets, at the same time reducing the sodium chloride by about two pounds and the calcium chloride by about two ounces. If this change proves satisfactory I again start, raising the strength of the baths as in the first instance, increasing the effervescence to three-quarters of a packet at about the sixteenth bath, and a whole packet at the twentieth The number of baths taken in a course varies from about 25 to 30 any greater number being, in my experience, likely to weaken the patient and to decrease rather than to increase the good that has been done. By the end of the course the patient is having a bath containing from 12 to 14 pounds of sodium chloride, from 14 to 16 ounces of calcium chloride, and one boxful of Sandow's effervescing tablets

Duration of immersion—As I have previously said, I begin by giving a three to four minutes' bath and with an average case I find that the best plan is to lengthen the time of immersion by one minute every second bath, curtailing it, however by two or three minutes when the first effervescing bath is given.

Temperature of baths.—The first bath is given at a temperature of 97° or 98°, this temperature being lowered 1° every second bath down to 94° or even 93° in exceptional cases, but it is often found that a good reaction cannot be obtained with a temperature below 96° and in these cases that temperature is adhered to throughout the course. At Nauheim, where the treatment is only given from the beginning of May to the end of September baths of a lower temperature may have some advantages, but it is my experience that a good reaction is not obtained from a bath given at a lower temperature than 93°

The administration of the exercises.—The exercises should be given by as experienced an operator as possible and by one who has been trained to watch the pulse and to regulate the resistance given by the effect produced. If increased arterial tension and rapidity of pulse are produced then the exercises are being given too forcibly and too rapidly and are doing harm rather than good. As a rule, if the exercises are properly given, they rarely fail to lower the rate and tension of the pulse and to increase its volume. I only give the exercises on the days when there is no bath taken, as I believe this is the wisest plan to pursue all through the course I am certainly convinced that to give both bath and exercises on the same day for a longer period than the last week of the treatment is unwise and I am doubtful whether even this is advisable except in cases of very slight cardiac trouble The exercises are by no means as powerful an agent as the baths and if no experienced operator is procurable it is best to omit them entirely

The general care of a case during treatment is of great importance no definite rules can be laid down which would be suitable to all, but it is essential that the patient should absolutely give up business and social engagements and should, if well enough, take a prescribed amount of walking exercise both morning and afternoon and have the digestion and bowels well attended to That these general directions carefully carried out help to a satisfactory result is manifest, but that they are not in themselves enough to produce that result I have proved, as I have often given cases general treatment for some time before using the Nauheim baths and have failed to obtain improvement as rapid satisfactory, or lasting as that resulting from a course of baths and exercises

I have not entered here into a discussion with regard to the forms of cardiac disease most suitable for treatment, as that is not within the scope of this paper, but in advising the treatment and giving a prognosis as to the result it must always be remembered that an organically diseased heart cannot be converted into a sound organ by this or any other method of treatment but that a dilated and enfeebled heart with flabby muscular walls and imperfect contractile powers can be cured by this method in a way that, in my experience, is not possible by any other form of treatment the reason for this being that whereas digitalis and other allied cardiac tonics whilst stimulating the heart increase the arterial tension the Nauheim treatment produces a dilatation of the peripheral vessels by the baths and of the muscle vessels by the exercises, thereby lowering arterial tension and giving the heart a comparative rest

In conclusion, I would say that there is nothing new in the methods of procedure I have endeavoured to outline in this paper, but as I have not come across any similar description in the medical press, I trust that it may be of use to those who are anxious to give the Nauheim treatment a *trial and that it* may be the means of inducing some who have never practised it to do so for I am convinced that, if given in the manner I describe, the Nauheim treatment is one of our most valuable therapeutic agents in the treatment of heart disease

DIABETIC GANGRENE OF THE TOE, AMPUTATION OF THE TOE RECOVERY

BY CHARLES FISHER, M B, B S DURH., M R C S ENG, L.R C P LOND

ON Sept 17th, 1902, I was consulted by a stout elderly man who complained of the middle toe of his left foot causing him pain. Upon examination it was seen to be acutely inflamed and in a sodden condition, with a hard corn on the dorsal surface of the last interphalangeal joint. The history given was that the patient had always led a very active life and had enjoyed excellent health till about eight or nine years before when he had quinsy; since then he had always felt unduly sleepy and tired during the latter part of the day He had had the corn for a number of years, but it had never caused him any trouble till about a month previous to his seeing me, when it became painful and the toe swollen, the pain frequently keeping him awake at night. The toe was washed with a solution of carbolic acid (1 in 60) and dressed with cyanide gauze, but the condition did not improve and by the 21st the skin covering the last two phalanges was purple in colour and sensation was somewhat diminished By the 23rd this portion of the toe was quite black and there was an entire absence of sensation Upon asking the patient if he had been suffering from inordinate thirst, had passed more urine than formerly, or had had an increased appetite, I received a negative answer to each question. His tongue was clean and moist, his teeth were good but much discoloured, and his bowels were opened regularly every day The liver was not enlarged The heart and lungs were normal, the pulse was 76, regular, of good volume and tension, the vessels were not thickened The skin of both feet was somewhat harsh and dry Upon examining the right foot the distal portion of the last phalanx of the middle toe was dark brown in colour, horn-like in structure, and devoid of sensation The patient said that this toe had been in much the same condition for the last two or three years The urine was rather pale in colour acid, of specific gravity 1038, and contained much sugar, but no albumin or excess of phosphate, and no diacetic acid Diabetic food and half a grain of codeia three times a day were ordered The quantity of urine passed for a number of days averaged 80 ounces and the quantity of sugar 1440 grains, the amount not being diminished in spite of treatment. By the 26th the line of demarcation was forming on the dorsal surface at the first interphalangeal joint, whereas on the plantar surface it was as far as at the metatarso phalangeal joint The toe was now being dressed with boric lotion (ten grains to the ounce) and cyanide gauze. During this time the patient was taking his food well and sleeping well, his temperature was not raised and his pulse was 80 Pulsation could be felt in the dorsalis pedis and posterior tibial vessels, but it was weak.

From this date onwards the condition of things gradually became worse, the foot becoming swollen and inflamed and a most offensive odour proceeding from the toe His temperature was 99 8° F and his pulse was 90 By Oct 4th the line of demarcation had completely formed and on the 6th Mr H F Waterhouse came down from London in consultation and amputated the toe at the metatarso-phalangeal joint. There was free hæmorrhage and a considerable amount of pus escaped As the foot was in such an inflamed condition a counter opening was made on the dorsum of the foot and a gauze drain was passed through. The flaps of the wound were not sutured together, but it was well packed with cyanide gauze After the operation the leg was kept well elevated and protected by a cradle The distal phalanx was found to be completely necrosed. From the following day and onwards until the inflamed condition of the foot had subsided it was dressed with warm boric fomentations, since then with cyanide gauze and boric lotion (10 grains to the ounce) On the 8th the wound was again offensive and gangrene appeared in the deep part of the wound, but fortunately it did not spread to any great extent and by degrees separated in the form of a slough After the operation the patient was ordered in addition to the codeia, a quarter of a grain of hydrochlorate of morphia three times a day and within a few days from taking the morphia the amount of sugar in the urine became less, the dose of both drugs was increased until the patient was taking three grains of each daily The wound and sinus filled up very slowly with granulation tissue and by Christmas they were quite healed, on which day the patient came downstairs for the first time since the operation. During the first week of being downstairs the urine was quite free from sugar, but ever since then there has been a slight amount present, the specific gravity being 1020 When the patient had been downstairs for a few days the dorsum of the foot became œdematous and this condition persisted for about a month, but as this began to subside œdema began to appear in the leg and it still exists During the latter end of January the gangrenous portion at the distal end of the middle toe of the right foot separated, leaving healthy skin underneath Since the beginning of the illness in September small pustules and purpuric spots have frequently appeared on various parts of the body and extremities. The patient is now leading a fairly active life and is able to attend to his business

This case presents several points of interest in that the classical symptoms of diabetes were absent the patient was a stout man and had not lost flesh, had not suffered from thirst, increased appetite, or passed an excess of urine, moist gangrene occurred on the left foot, dry on the right, and the corresponding toes were affected as in Raynaud's disease. The patient had had no business or family trouble and all his relatives had been healthy living to an old age, with the exception of a maternal uncle who died from gangrene, but whether diabetic or not is not known.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF BLACKWATER FEVER TREATED WITH LIQUID EXTRACT OF CASSIA BEAREANA.[1]

BY DR. H. CORKE,

MEDICAL OFFICER TO THE ZANZIBAR GOVERNMENT IN PEMBA.

I RECEIVED an urgent call on Jan. 26th, 1903, to proceed to Weti, some 18 miles away, to attend a woman engaged in missionary work who was said to be suffering from blackwater fever I accordingly saw her on Jan. 27th She had been invalided home some years before for an attack of blackwater fever She had been suffering on and off from attacks of ordinary malarial fever for some time previously to my seeing her and had been taking sulphate of quinine. I learned that on Jan. 26th her urine had suddenly assumed a very dark appearance and had become very scanty in quantity Her temperature at that time was 105° F She had pains all over the body and there was a tendency to jaundice During the night of the 26th she had several fits of vomiting and she slept only in snatches of a few minutes at a time. On the morning of the 27th general jaundice was well marked the conjunctiva being very yellow, with pains all over the body, the urine was quite black, scanty in quantity, and was passed frequently, the temperature was 103° and the pulse was 88 per minute, strong, and regular. As the bowels were constipated I administered three grains of calomel. I prescribed 15 minims of liquid extract of cassia Beareana well diluted with water, to be given every half hour at first and afterwards every hour For nourishment Brand's extract of meat was given To allay the thirst from which the patient was suffering I prescribed rice- and barley water I gave champagne occasionally in small quantities After the first dose of cassia Beareana all vomiting ceased, the patient dozed on and off throughout the day, and the temperature fell gradually from 103° at 11 A.M to 99 8° towards evening, when an enema was administered which acted fairly The patient passed a much better night, had no headache, and slept at intervals On the morning of the 28th her temperature was 100°, the jaundice was still very marked, and her pulse was 90 per minute, good and regular She vomited some bile at 6 A.M. and an enema was administered which produced a large motion, constipated in character and containing scybalous lumps Cassia Beareana was administered every hour during the day Towards evening a distinct improvement was observable in the urine voided, which was fully 50 per cent. lighter in colour than it had been in the morning The temperature remained at 100° all through the day, there was no vomiting, and the patient took nourishment well. On the 29th the jaundice steadily diminished, the urine became practically normal in colour, and the tongue was less furred. The dose of cassia Beareana was diminished to ten minims administered every two hours. The temperature ranged from 100° to 101° during the day, there was no vomiting The patient took nourishment freely and slept much in the course of the day The urine voided towards evening was quite clear On the 30th it was found that the patient had passed an easy night. The temperature was 101°, the jaundice had practically disappeared, and the urine was clear and was passed freely As all the urgent symptoms had now disappeared I left the patient in charge of an experienced nurse with instructions to continue the cassia remedy and to communicate with me should any fresh symptoms arise.

---

[1] A full account of the botanical characters and medicinal properties of cassia Beareana, by Dr D R O Sullivan Beare and Mr B M. Holmes, F L.S was published in THE LANCET of Feb 1st, 1902, p. 282

I am of opinion that recovery was due solely to the beneficial action of the drug given—namely, liquid extract of cassia Beareana—the patient being advanced in years and this being her second attack I should most decidedly administer the same drug should I ever meet with any more cases of blackwater fever and I would give it with the greatest confidence.

Chaki Chaki, Pemba.

A CASE OF FULMINATING APPENDICITIS WITH SEPTIC PERITONITIS

By F E WOOD, B A., M.B, B C CANTAB.,

HOUSE SURGEON TO THE WINDSOR AND ETON ROYAL INFIRMARY

THE following case presents one or two points of interest, he chief one being the distance travelled in the removal of he patient to the infirmary This was done with ease under he influence of morphia and with apparently no ill effects.

The patient, who was a female, 26 years of age, was perfectly well on Dec. 4th and first came under medical observation on Dec. 5th on account of pain in the "stomach." On examination slight pain and tenderness with a certain amount of dulness were found to exist in the right iliac region. Her pulse rate was 90 and her temperature was 99° F On the following day the symptoms were much the same. On the 7th less than 48 hours from the commencement she complained of great pain in the right iliac region and it was then found that there were tenderness and dulness in the right flank, tympanites and loss of liver dulness Her temperature was 101° and her pulse-rate was 130 A diagnosis of perforation of the appendix was made. She was then put well under the influence of morphia and removed a distance of two and a half miles to the infirmary The removal was borne very well On admission the patient complained of no great pain, the physical signs were the same as above enumerated. A consultation was held at which the previous diagnosis was confirmed and an operation was decided upon.

The operation was performed on Dec 7th by Dr E. S. Norris, senior surgeon to the infirmary An incision was made over McBurney's point about three and a half inches in length. On opening the peritoneal cavity a quantity of offensively smelling pus escaped but there was no free gas. Some coils of intestine covered with flakes of lymph were floating free in the fluid There was also some matting together of the other coils and on breaking down a few adhesions pockets of a clearer fluid were found The appendix was not seen, so no attempt was made to remove it. The peritonitis extended right down into the pelvis and as far as the hand could reach in the abdomen The cavity was then washed out with warm boric lotion of the strength of 1 in 40 During this process the patient, who had been anæsthetised with chloroform, stopped breathing, whereupon artificial respiration was performed and injections of strychnine and ether were given. The washing out was also stopped. When she had recovered somewhat a Keith's glass drainage tube was inserted right down into the pelvis and absorbent dressing was applied over this. She was then removed to the ward. She had recovered from the effects of the anæsthetic but was very collapsed, so further hypodermic injections of strychnine and ether were given and also a nutrient enema containing two ounces of brandy and the yelk of one egg Some time afterwards she vomited twice and in the evening passed a well formed motion Rectal feeding was continued every two hours for two days On the second day after the operation feeding by the mouth was begun and as no vomiting occurred this was continued in gradually increasing quantities, peptonised milk, eggs, and brandy being given The bowels were kept open by injections of two drachms of glycerine about every other day. The day after the operation the patient's general condition was fairly good but she had the facies abdominalis well marked The wound was dressed frequently and about three ounces of offensive pus were withdrawn daily by the syringe. The glass tube was kept in for a week and then an indiarubber one was substituted. During the first week the whole thickness of the abdominal wall, about an inch in width for the entire length of the wound, sloughed away and the bowel was seen at the bottom of the wound. The patient progressed well from this time and is now quite well, the wound having healed completely

Windsor

NOTE ON CONDITIONS MODIFYING EXANTHEMATOUS ERUPTIONS

By JOHN REID, M A., M.D ABERD

IN medical practice there is often a temptation to diagnose a recrudescence of a previous attack, or even a fresh zymotic disease, on the appearance of a fresh eruption while probably sight is lost of certain factors in connexion with such cases—namely, (1) the fact that the skin has passed through an inflammatory stage and is on that account a *pars minoris resistentiæ*, (2) that the zymotic disease may have attacked a constitution weakened by rheumatism or gout, where rashes often appear, and (3) that some local mischief may favour, or rather tend to induce, eruptions. As illustrating the above principles I trust the following cases will prove interesting

CASE 1—A girl, aged nine years, with a rheumatic diathesis suffered from a burn of the second degree on the leg covering an area two inches square. Bronchial catarrh and herpes on the face and eyelids preceded varicella The mouth was full of pustules and it was extremely difficult to feed the patient, as the state of the lips and mouth interfered seriously with movement and the irritation of food matters was great. Lichen urticatus and general desquamation followed the varicella Quinine and cod liver oil formed the dressing and the administration of an alkaline stomachic mixture completed the treatment

CASE 2.—A boy, aged 12 years, passed a tænia solium after a dose of male fern. In a week he had an attack of typical measles, with fever and bronchitis He was treated with an ammonia mixture. In this case also the rheumatic diathesis was present. Koplik and Filatow's spots were seen. The rash disappeared on the sixth day and on the following day an exactly similar rash without fever—erythema morbilliforme—suggested a return of measles. There was intolerable itching After replacing the ammonia mixture by a mild stomachic the rash and itching disappeared within 24 hours and were followed by desquamation

CASE 3.—A male child, 11 weeks old, suffered from proctitis with rectal prolapse and bubonocele of the left side.

The symptoms improved under lead lotion and belladonna and the internal administration of bismuth. Pneumonia of the left base came on, necessitating the administration of brandy Next followed typical measles with Koplik and Filatow's spots The measles lasted for six days and then pneumonia returned in the left base A speedy desquamation followed. An erythema of one day's duration came on and finally herpes over the left groin and left buttock, as well as near the anus and on the anterior third of the penis The prepuce was inflamed and required treatment. Further symptoms were gastro intestinal catarrh with green clayey motions and protracted convalescence joined to slight bronchitis, although the child rapidly put on flesh and drank milk heartily This child as well as the other members of the family, had rheumatic symptoms It should be stated that snuffles were present although no other signs of specific disease presented themselves. The teeth of the other members of the family were good and regular as to time The father and mother were healthy

ST GEORGE'S HOSPITAL

A CASE OF EXTENSIVE PERICARDIAL EFFUSION, OPERATION, RECOVERY

(Under the care of Dr ARTHUR LATHAM and Mr H S PENDLEBURY)

A MAN, aged 53 years, came under the care of Dr Arthur Latham on Sept 1st, 1902 at St George's Hospital. He gave a history of good health until the early part of last March. He denied having had syphilis and asserted that he had always been a moderate drinker In the early part of March he began to suffer from shortness of breath This symptom gradually became more troublesome and the patient in consequence was obliged to give up work on March 28th. On April 4th the left pleural cavity was tapped and ten ounces of serous fluid were withdrawn. Further small quantities of blood stained fluid were removed on May 23rd, July 22nd, and August 5th During August the patient developed marked œdema of the legs and some distension of the abdomen He also became jaundiced. When he attended at the hospital he complained of sleeplessness and of cold extremities. He was suffering from considerable dyspnœa, with slight cough and expectoration, the face was sallow and somewhat cyanosed, the pulse-rate was 76, the volume being small and the wave full though regular, the respirations were 24 to the minute, the temperature was normal. The legs were markedly œdematous and there was evidence of a considerable quantity of free fluid in the abdominal cavity The apex of the heart could not be felt nor could it be located by the stethoscope as no cardiac sounds could be detected, the area of cardiac dulness was much increased. The note over the left axillary base was dull, there was diminution of the voice sounds, and on auscultation distant tubular breathing was heard Over the base of the left lung posteriorly the note was impaired, there was distant tubular breathing, and a few moist sounds could be heard The urine had a specific gravity of 1028, was normal in colour, somewhat diminished in amount, and contained a very faint trace of albumin On Sept. 3rd the patient was given a little chloroform by Dr Ll Powell Mr H S Pendlebury *tapped* the pericardial sac in the fourth costal interspace one and a quarter inches from the left border of the sternum and drew off 95 ounces of serous fluid which was dark brown in colour owing to the presence of a considerable quantity of methæmoglobin. No further evidence was obtained by a careful examination of the fluid. The patient slept well during the night and felt much more comfortable on the following morning The heart sounds could now be heard over the præcordial area but were still very faint. During the night 90 ounces of urine were passed. On the 8th the patient was comfortable and the œdema of the legs and the distension of the abdomen were considerably less. He was sleeping well and the coldness of his extremities had diminished. The pulse was of good quality and the wave could be easily felt. The heart sounds, however, were again becoming more distant and the cardiac dulness was again increasing, consequently Dr Latham asked Mr Pendlebury to drain the pericardial sac, which apparently had been distended with fluid for several months and was still secreting to an appreciable extent.

The operation was performed on Sept. 9th Having decided to drain the pericardium for some time it was of *the first importance to choose a procedure* which would insure drainage from the lowest approachable part of the pericardial cavity Consequently Mr Pendlebury determined to perform the operation so clearly described by Dr Cyril Ogle and Mr Herbert Allingham in THE LANCET of March 10th, 1900, p 693, with such modifications as might appear necessary A vertical incision some four and a half inches long was made with its centre at the lower border of the seventh costal cartilage parallel with, and one inch from, the left border of the sternum. The skin and fascia were reflected inwards and outwards and the abdominal muscles were then detached from the seventh costal cartilage The cellular interval, "costo-xiphoid space," containing the superior epigastric artery was then broken into, some of the muscular fibres of the diaphragm being torn. As the pericardium was distended it was easily brought into view, but as Mr Pendlebury wished to have sufficient room to insert the fingers after opening it two inches of the seventh costal cartilage were first removed by cutting it through with bone forceps and disarticulating the fragment from the sternum. The internal mammary vessels were now exposed and held aside. Had it been necessary it would have been easy to secure them More loose connective tissue, fat, and the triangularis sterni were gently pushed aside and the pericardium—tense and thick—was exposed Owing to the conformation of the chest the wound was somewhat deep and to obtain more complete and convenient access to the pericardial contents after opening two inches of the sixth costal cartilage were likewise removed. The pericardium was incised where it bulged downwards through the torn cellular space and the cut edges were seized with clips Some 20 ounces of blood stained fluid, similar to that removed by tapping on Sept. 3rd, escaped The incision into the pericardium was increased to allow of three fingers being introduced to examine as far as practicable the heart and parietal pericardium These were found quite smooth and apparently normal Unfortunately, the man's chest was very deep and it was not possible to explore thoroughly the back of the heart and pericardium, as can be done so readily in children after this operation There were no adhesions to be felt and the fingers could be interposed between the heart and the diaphragm A peculiar vibratile thrill was noticed on palpating the ventricles during systole. These manipulations had no harmful effect on the pulse, indeed, the escape of the remaining fluid had distinctly increased its strength and promoted its regularity It was only possible to stitch one corner of the pericardium to the skin at the lower end of the wound, a tube was introduced and the upper three inches of the incision were united by silkworm gut sutures The tube was removed on the fourth day after the operation as it was blocked with the clotted discharge On the eighth day the 16th, the stitches were removed, only a small sinus remaining where the pericardium had been sewn to the skin This sinus did not completely heal till nearly three weeks afterwards, a little easily clotting fluid trickling away from time to time. Throughout convalescence the patient's temperature was normal On the 16th the patient had improved to an extraordinary extent He was sleeping well and was free from dyspnœa, there was hardly any œdema of the legs, and there was no *evidence of the* presence of fluid in the abdomen The percussion resonance of the sternum was normal and there was no extension of dulness to the right of the sternum The cardiac sounds could be heard distinctly and the position of the apex appeared to be normal, although the thickness of the patient's muscles made an exact localisation impossible. Towards the base of the left lung there was some impairment of the percussion note, the vocal fremitus was increased, and the heart sounds were high pitched, whilst near the vertebral column distant tubular breathing could be heard. The urine was acid and pale, the specific gravity being 1008, no albumin could be detected after Sept. 19th. From Sept. 29th to Oct. 8th the daily output of urea varied from 216 to 463 grains The patient made an uninterrupted recovery, going into the hospital yard on Oct. 8th and to Bexhill on the 23rd Writing on Jan. 22nd, 1903, he stated that he felt perfectly well and was able to do his work

Remarks by Dr LATHAM and Mr PENDLEBURY —The above case is of interest in view of the facts that so large a quantity as 95 ounces was removed by aspiration from the pericardial sac in one operation, that the pericardial sac was opened by means of a new method devised by Mr Allingham and Dr Ogle, and that the patient is now well and at work The pleura was not seen at all during the operation and probably it may be taken that in cases where the pericardium is distended with fluid it is not likely to be seen. If it did come into view it could easily be held aside with the finger It may be suggested that by beginning the incision into the pericardium at a level just above the base of the ensiform cartilage all danger of opening the abdominal cavity is avoided. Surgically speaking, it may be said that the operation is not difficult to do and only takes a little over 20 minutes It would seem advisable, however, in cases where a large amount of fluid exists, to withdraw some before the actual operation in order to relieve a little the heart's embarrassment. Since writing the above we are permitted to mention that Mr Allingham has performed the operation on two other cases with success

Medical Societies.

CLINICAL SOCIETY OF LONDON

Skin-sliding as a Means of preventing and removing Cicatricial Deformity —A Case of Spinal Caries treated by Costo transversectomy with Complete Recovery —Prolapse of the Bowel and Prolapse of the Uterus treated by the Injection of Paraffin

A MEETING of this society was held on March 13th, Mr HOWARD MARSH, the President, being in the chair

Mr T. S. ELLIS (Gloucester) read a paper on Skin sliding as a Means of preventing and removing Cicatricial Deformity The process consisted of a daily dressing or massage by means of pinching up the skin around the edge of a wound or a scar and thus stretching or sliding the skin and subcutaneous tissues in the direction required The process was devised by Mr Ellis in the belief that when the skin in the neighbourhood of a cicatrising wound was made to slide freely and all adhesion of the cicatrix at the margin of the wound to the tissues beneath was prevented the contraction of the cicatrix, acting on the skin, would draw it towards and over the area of the wound Interstitial growth in the extended skin compensated for the extension it had undergone For the effacement of a cicatrix of any kind (keloidal or other) not only was the attainment of freedom from attachment indicated but also such mobility and redundancy of skin around it as should for a time, give freedom from tension. This indication might often be completely fulfilled by persistently sliding the adjacent skin towards the cicatrix and using the skin (made redundant) as a handle wherewith to lift the cicatrix from its attachment Lantern slides were exhibited of a case of severe burn which had occurred on Jan. 15th, 1902, to a child, aged 11 years, involving extensive destruction of the integument of the neck and chin, and the advantages of the treatment were described. Some calipers which Mr Ellis had designed to aid the process were also exhibited —Mr. A. E. J BARKER recalled an investigation by a committee of that society on keloid which had come to the conclusion that keloid sometimes underwent spontaneous cure. He then referred to a case in which skin grafts had been followed by such rapid growth of keloid that it was thought to be sarcoma, though the subsequent history showed that it was not so —Dr W H. B BROOK asked what was the exact manner of picking up the skin and for what period of time it had to be picked up.—Mr. ELLIS replied that no knife was required.

Dr W H. B BROOK (Lincoln) read a paper on a case of Total Paraplegia due to Caries of the Mid-dorsal Vertebræ, for which the Operation of Costo-transversectomy was performed with complete recovery The patient, a youth, aged 17 years, was admitted into the Lincoln County Hospital on Sept 22nd, 1902, suffering from angular curvature of the spine of a year's duration, for which he had worn a plaster jacket. During the previous four weeks there had been gradually increasing loss of power in the legs, with incontinence of urine. When admitted he presented well marked angular curvature, the sixth and seventh dorsal spinous processes being the most prominent. There were no tenderness and no signs of any collection of pus. There was well marked girdle sensation at the level of the epigastrium, with great impairment of sensation below this level. The legs could be moved but not well, the knee-jerks were exaggerated and there was incontinence of urine. For six weeks he was treated by extension applied to both legs, but his condition became steadily worse, paraplegia and incontinence of urine and fæces gradually became complete, and in spite of the greatest care bedsores appeared A skiagram showed blurring in the region of the seventh and eighth dorsal vertebræ, confirming the diagnosis that tuberculous matter was present. On Nov 8th the operation of costo transversectomy, as described by Mr J. Jackson Clarke, was performed, the right transverse process of the eighth dorsal vertebra being cut down upon and removed together with the head and neck of the eighth rib so that access was obtained to the seat of the disease and the broken-down bodies of the vertebræ were carefully scraped away with a specially designed curved sharp spoon, care being taken not to wound the dura mater or the pleura The wound was drained, injected with iodoform emulsion containing 1 40 per cent. carbolic acid, and tightly packed with iodoform gauze. The extension was continued Sensation began to return on the following day and movement on the day after At the end of three weeks sensation was perfect and movement was good but it was seven weeks before the patient regained perfect control over the bladder and rectum. The drainage-tube was discontinued on Jan. 8th the wound was healed by Jan. 25th and on Feb 15th the patient was able to sit up after having been fitted with a steel spinal support. He was now able to walk quite well.—Mr JACKSON CLARKE related how he first came to perform the operation that Dr Brook had so successfully repeated In October, 1901 a patient, aged 45 years, rapidly developed total sensory and motor paraplegia from tuberculous disease of the seventh and eighth dorsal vertebræ. Mr Jackson Clarke performed laminectomy and found that an abscess (formed by the destruction of the posterior parts of the bodies of the two vertebræ) was pressing backwards on the cord To secure better drainage he performed costo-transversectomy seven days after the first operation The result was most satisfactory and showed that the second operation would have done all that was required without the preliminary laminectomy From this experience and that of three other cases Mr. Jackson Clarke came to the conclusion that the removal of the transverse process afforded the best means of access to the vertebral bodies in certain cases. When complete sensory and motor paralysis came on rapidly as in his first case the lateral drainage, whether by removal of a transverse process alone or in conjunction with the head and neck of a rib, should be done at once. When the symptoms were not urgent rest should be tried for some months before proceeding to operate The main object of the operation was to open the abscess and to establish an aseptic sinus through which a few drops of carbolic solution or some other antiseptic could be injected daily for as long as might be necessary No attempt should be made to scrape away caseous material or carious bone The cord was often exposed by destruction of the bodies of the vertebræ and such interference would be highly dangerous If the paralysis should not be relieved the subsequent performance of laminectomy was in no way interfered with by the lateral opening —Dr BROOK, in replying expressed a preference for a straight spoon.

Mr. STEPHEN PAGET read a paper on Two Cases of Prolapse of the Bowel and a Case of Prolapse of the Uterus treated by the Injection of Paraffin under the Mucous Membrane The first case was that of a man, aged 65 years, who in 1897 had undergone excision of the rectum for cancer Ever since the operation he had suffered from prolapse of the bowel with loss of control and had been compelled to wear a rectal plug On Jan. 15th paraffin was injected into the prolapsed bowel, forming two hard round nodules under the mucous membrane, so that the opening into the bowel was closed by a sort of valve Since then there had been no prolapse, the patient had left off his plug and had kept perfectly clean. The second case was that of a patient of Dr E Lycett Burd of Shrewsbury She was 70 years old and had suffered from prolapse of the bowel for 22 years and had undergone five operations Prolapse occurred on the very least effort and if the motions were loose she had no control over them. On Feb 15th paraffin was injected under the mucous membrane, forming a hard collar around more than half of the bowel, this produced great improvement, but there was still slight prolapse at times On March 1st a second injection was made and the opening into the bowel was also narrowed by Mayo Robson's incision and suture This second operation was followed by some severe pain, but no prolapse had occurred since it was done The third case was that of a woman, aged 63 years, who for 28 years had suffered from prolapse of the uterus in spite of an operation which had been performed 14 years before. The prolapse occurred even when she was in bed, if she only coughed or turned over By day she supported it with a napkin The vagina was so greatly dilated that it would not retain a pessary and there was complete prolapse of both walls and of the cervix which was greatly enlarged. On Feb 25th paraffin was injected in various directions under the mucous membrane of the vagina, mostly in the posterior wall, and under the mucous membrane of the cervix. Since this injection she had had no prolapse, not even when she strained at the closet or "bore down" forcibly in the erect posture. The cervix was high up, both walls of the vagina were indurated, and the recto-vaginal septum was about half an inch in thickness. Mr Paget said that he brought these cases thus early before the society because he felt sure, from his experience of the use of paraffin in 40 cases of sunken nose, that the good results in these cases of prolapse would be well maintained. If it were at any time necessary to add a little more paraffin this could easily be done.—Mr BARKER mentioned a case of prolapse of the rectum in which he had adopted this method with complete success He had used a mixture of paraffinum molle and olive oil. A small celled infiltration resulted which aided in achieving the result In the hands of some surgeons embolism and other disasters had resulted.—Dr G H D ROBINSON had seen Mr Paget's case of prolapse of the uterus and the success was certainly quite remarkable. The operation was not suitable unless the patient had passed the child bearing period, but in other cases this method offered every prospect of success —Mr GEORGE EASTES asked if it was necessary to keep the stools liquid or not in cases of rectal prolapse.—Mr PAGET, in replying, said that the bowels should not be relaxed, rather the reverse. He thought the possibility of disaster had been exaggerated. If cases were treated as out-patients and 15 cubic centimetres of paraffin were injected at one sitting or the wax was too soft it would not be surprising that embolism should result. The melting point of paraffin was of considerable importance, it should not be below that of the body temperature. Reference was made to the case of a man in whom the absence of testicles was compensated for by the introduction of paraffin and who subsequently had typhoid fever accompanied by a temperature of 105° F, when the wax began to melt. The melting point Mr Paget preferred was between 111° and 115°

SOCIETY OF ANÆSTHETISTS

New Form of Chloroform Regulator —Apparatus for administering Ether, Chloroform, or Mixture

A MEETING of this society was held on March 6th, Mr WALTER TYRRELL, the President, being in the chair

Mr A VERNON HARCOURT, F R S, read a paper on his new Chloroform Regulator

The PRESIDENT, in introducing Mr Harcourt, said that he (Mr Harcourt) had been good enough to send them a report of a paper which he had read before the Royal Society on the Percentage Dosage of Chloroform. Since then he had been invited to become a member of the committee of the British Medical Association on the dosage of chloroform and had asked that committee to allow him to show his apparatus and to read a paper on the percentage dosage of chloroform before the Society of Anæsthetists. He would now ask Mr Harcourt to read his paper

Mr HARCOURT said that during many years past he had been concerned with the measurement of light and to provide a standard light for this purpose he had used a volatile hydrocarbon which was called pentane as being the fifth member of the series of paraffins. In dealing with this liquid he had accidentally inhaled some of its vapour and observed that it produced sensations similar to those caused by the inhalation of small quantities of chloroform Since the substance was readily obtained in a nearly pure condition, was little liable to chemical change, and was almost insoluble in water, it occurred to him that it might be serviceable as an anæsthetic. With the coöperation of Professor Gotch the trial of its physiological properties was made by giving white rats a mixture of air and pentane to breathe Anæsthesia was readily produced, but it was preceded by a period of excitement, the proportion of vapour to air required was rather large, involving, of course, a corresponding diminution in the proportion of oxygen, and recovery was slow and uncertain The results of the inquiry formed the subject of a paper read by Professor Gotch before the Physiological Society in 1898. To form a judgment of the effects of pentane upon rats as compared with those of another anæsthetic chloroform was administered in the same manner, and he might confess to having been a little disappointed when it appeared that chloroform was the better anæsthetic of the two In making these experiments it seemed desirable to find some means of regulating the proportion of air and of anæsthetising gas and of determining what the proportion was. Confining himself now to the case of chloroform Mr Harcourt tried a method of determination depending upon the action of a hot alcoholic solution of potash. The results were approximately right, about 95 per cent. of the chloroform, of which a weighed quantity had been brought into a flask filled with air, was represented by potassium chloride in the solution. But whatever care was taken the result was always a little too low and he therefore sought, and succeeded in finding a better method. When a platinum wire was heated to bright redness by the passage of an electric current in a mixture of air, chloroform, and steam, the chloroform was burnt on the surface of the platinum by the oxygen of the air and the chlorine which was probably formed in the first instance reacted, also under the influence of the heated wire, with the steam, forming hydrochloric acid and oxygen A small quantity of water placed in the flask containing the mixture of air and chloroform served both to supply steam when the bottom of the glass was heated and to dissolve the hydrochloric acid which was formed. After 20 minutes the operation was completed and it remained only to determine the amount of hydrochloric acid in the flask, which might be done by means of a standard solution either of silver nitrate or of alkali A full account of this method, and the record of the testings with weighed amounts of chloroform by which its trustworthiness was established, was given in the Transactions of the Chemical Society for 1899 In the same paper there was also described a method for charging a current of air with a proportion of chloroform vapour which might be fixed at any desired limit This method consisted in sending a stream of air through a mixture of alcohol and chloroform and then through water If the mixture contained only a small proportion of chloroform, then but little chloroform evaporated into and mixed with the air, if the proportion of chloroform in the liquid was larger the amount that evaporated was larger also. By passing the mixture of air with the vapours of alcohol and chloroform through or over water the alcohol was removed, and only air and chloroform passed on in a proportion determined by that of chloroform and alcohol in the liquid mixture. That the liquid used for diluting chloroform in order to diminish its rate of evaporation should be itself volatile was advantageous since when the quantity of both liquids diminished as evaporation proceeded the composition of the mixture remained more nearly constant than if only one was evaporating After writing this paper it occurred to him that a method might be made on the same principle for the administration of chloroform as an anæsthetic In order to provide for its administration in sufficient quantity and with a minimum respiratory effort he changed the form of the apparatus. If air travelled over a liquid for a sufficient distance saturation was complete and the resistance was far less than if the air bubbled through.

Mr. Harcourt had found by trial of various proportions that a mixture of 80 parts of alcohol by weight with 20 of chloroform yielded when air was passed over it a mixture of 98 volumes of air with two of chloroform vapour. He had found, and subsequent experience had confirmed the conclusion, that 2 per cent. of chloroform was the maximum amount ever required in producing anæsthesia. To reduce this proportion to any smaller proportion that might be desired he made an arrangement of stopcock and valves by which the 2 per cent. mixture might be diluted to any amount with pure air a pointer moving on a scale indicating the percentage thus produced. This apparatus was tried at the Oxford Infirmary by Dr. A. P. Parker, a surgeon who had had large experience of anæsthetics during the South African war. The tank filled with water which held the two boxes containing respectively alcohol mixed with chloroform and water was supported on a staging beneath the trolley on which the patient lay and the face-piece was connected with the outlet of the apparatus by caoutchouc tubing. The management of the amount of chloroform administered presented no difficulty and the result was satisfactory, but Dr. Parker represented to Mr. Harcourt that for ordinary medical use a portable apparatus was necessary. For this purpose the limitation of chloroform by dilution had to be given up, and Mr. Harcourt substituted for it a limitation of the surface of chloroform from which evaporation took place. After trying vessels of various size he found that air passed at the ordinary rate of human respiration through the upper part of a bottle containing chloroform the diameter of which was about 1⅗ inches took up 2 per cent. of chloroform. This proportion did not vary as might be expected with the rate at which air was drawn through. When the air entered the bottle slowly it passed from inlet to outlet without complete admixture with the air and chloroform lying over the surface of the liquid and thus a smaller quantity of air was mixed with a smaller quantity of chloroform. On the other hand, when air entered more rapidly it blew upon the surface of the liquid and caused more rapid evaporation, and thus a larger quantity of chloroform. The original instrument had the form of a straight stem to which the face-piece was attached, with branches connecting through a stopcock with this stem and at their other end with two valve-chambers one opening into the air and the other attached to a small Woulfe's bottle holding chloroform. The handle of the stopcock terminated in a pointer moving on a divided arc. According to the position the stem was connected either with one branch or the other or partly with both. A prolongation of the stem upwards ended in another valve-chamber which allowed passage to expired, but not to inspired air. Since the amount of evaporation depended not only on the area of liquid from which evaporation was taking place but also upon the temperature of the liquid, the operator must be provided with some ready way of observing the temperature. A thermometer could not be read very quickly and its insertion would require the provision of a third tubulure. Specific gravity bulbs were easily seen and answered the purpose well, since the density of chloroform changed rapidly with its temperature. By providing two bulbs, one of which was between floating and sinking when the temperature of the chloroform was 15° C. (59° F.) and the other when the temperature was 12·5° C. (54·5° F.), and placing these in the bottle with the chloroform it would be seen whether the temperature was above 15°, for then both bulbs sank, or below 12·5°, for then both bulbs floated. The temperature should be maintained as far as possible, between these temperatures, and when this was so one bulb was floating and the other sunk. Since anæsthetising and operation rooms were kept at much higher temperatures than 59° F. Mr. Harcourt used at first bulbs which were adjusted for several degrees higher, but the cooling of the chloroform by evaporation was so great that frequent applications of the hand to the bottle were needed to maintain the higher temperature. Also the proportion of chloroform with a bottle of the size he used was at a higher temperature, rather more than 2 per cent. Mr. Harcourt had made several other changes in this inhaler, to which he proposed to give the name of "chloroform regulator" since he read a paper on the subject before the Royal Society. To enable the face piece to be placed in any position he had divided the stem into two parts by a cross branch and had provided each part as well as the cross-branch with swivel joints. The longer piece of caoutchouc tubing connecting the chloroform bottle with one of the valve-chambers, which allowed the bottle to retain a vertical position when the stem was inclined, was now shortened, since the stem could be held upright. The upper valve-chamber had been removed and the valve transferred to the face-piece. This had the advantage of making expiration easier and limiting it to the face piece so that none of the patient's breath passed into the body of the instrument. The bottle had been made slightly conical, enlarging downwards, as the chloroform evaporated the interval between its surface and the air inlet necessarily increased and this was balanced by an increase of area. The valves consisted of discs of celluloid held in position by a short neck or continuous strip of the same material, the end of which was fastened down. By cutting this neck of a suitable width the spring which held down the disc against the tube which it covered might be made just sufficiently strong to support the weight of the disc in an inverted position. The movement of these valves gave useful information. That on the face-piece showed clearly whether respiration was full and regular, those connected with the two branches showed by the height to which they were raised how much of the 2 per cent. mixture was being inhaled and with how much air it was being diluted. The proportion was also shown by the position of the pointer on the divided arc. For example, if it was in the middle equal quantities were being inhaled of air mixed with 2 per cent. of chloroform and of pure air—that was to say, the mixture being inhaled contained 1 per cent. of chloroform. From any other position of the pointer upon the scale the percentage of chloroform which was being administered could be read off. Mr. Harcourt had been present at four or five operations at University College Hospital and, so far as he could judge or learn afterwards, the assistant to whom the management of the regulator was committed found no difficulty in maintaining the desired degree of anæsthesia. The proportion of chloroform required to produce anæsthesia in from five to ten minutes was with adults between 1 and 1·5 per cent. and for its maintenance subsequently between 0·5 and 1 per cent. He thought it possible that the actual figures should be lower than these some uncertainty arising from imperfect fitting or occasional displacement of the mask. But here he was on unfamiliar ground, and he hoped that an account which would be much more trustworthy of the use of the regulator and its advantages as compared with other apparatus or methods for administering chloroform would be given to the society by its President, to whose encouragement during the past two months he was greatly indebted.

The PRESIDENT said that the Society of Anæsthetists was much indebted to Mr. Harcourt for his paper and for the very lucid description of the methods by which his conclusions were arrived at. The idea was one "oft thought before but ne'er expressed so well." Mr. Harcourt had done what had been in all their minds to do but no one had quite accomplished it. Half a century ago Dr. Snow invented an inhaler with two orifices through which the inspiration was made, through one of these the inspired air passed over chloroform and the other was an inlet for pure air, and by slowly diminishing the size of the latter more and more of the inspired air passed over the chloroform until the desired anæsthesia was produced. This was exactly what Mr. Harcourt's apparatus did but nobody before had been able to show approximately what percentage of chloroform was being inhaled at any given moment. The credit of doing this must be given entirely to Mr. Harcourt. Mr. Clover had given them a percentage of chloroform but without any accurate means of regulating it. Junker's inhaler with its many modifications made mostly by members of their society and various other methods all tended towards the desired end of regulating the quantity of vapour inhaled, but it was only now that they had learned what the percentage really was. Perhaps those present who had used Mr. Harcourt's apparatus would give their experience of it. He (the President) had been much impressed with it and although he thought the arrangement of it was capable of improvement he believed that the principle of it was good and would prove of great service. The President then gave in detail notes of a few cases in which he had used this new instrument. He said that a child aged three years and eight months had been satisfactorily anæsthetised for an operation on the elbow and glands of the neck without ever exceeding 0·5 per cent. of chloroform. He had had several adult cases including iridectomy for glaucoma, removal of the breast, appendicectomy, &c. which had not required more than 1 per cent. and in no case had any patient of his required the maximum amount of 2 per cent. In one case pallor and failing pulse occurred while using 1 4 per cent, which was an instance of what could not be too strongly insisted on—viz., that a percentage only sufficient to produce anæsthesia was dangerous to a certain number of individuals The most striking thing about the administrations was the greatly diminished amount of excitement—in fact, in several cases this was entirely absent.

Dr DUDLEY W BUXTON said that the society was much indebted to Mr Harcourt for the very clear way in which he had led them to understand that which had put the idea of the apparatus into his mind But they had before them that night an actual dosimeter of chloroform Perhaps the President had not done justice to Clover in saying that there was no accurate method of giving a definite percentage of chloroform. In the apparatus before them they had certainly a means by which they might accurately and definitely know a percentage of chloroform There was one idea they, as practical men, had to dispute—i.e., that 2 per cent. of chloroform was capable of carrying them through all exigencies. Affairs such as they had to face to day in the operating theatre were very different from those of 50 years ago In those days operations which required a death like stillness were not performed and absolute quietness of the patient was neither asked nor expected Not only were they now asked to render the patient anæsthetic but to push narcosis to such an extent that vitality was distinctly lowered They were asked to act on the medulla oblongata and narcosis had to be pushed thus far in order that the surgeon might carry out his operation They (the anæsthetists) had to do as they were told He was quite sure that 2 per cent. would not carry them through all operations Would it not be possible to alter the apparatus in order to provide a 4 per cent. vapour if such were required? The experience which he had had with the apparatus had agreeably surprised him, more particularly as he was somewhat averse to new chloroform regulating inhalers, as so many had been failures None of them expected to give chloroform with absolute safety and most of the apparatus had fallen short in some important detail With Mr Harcourt's he had expected to have moderate success, but the success obtained had exceeded his expectations It produced a quiet anæsthesia, little or no struggling and the patients had gone under with a low percentage, beginning with 0 5 and sometimes 0 25 per cent. Dr Buxton then said that in a case of abdominal section for gastro enterostomy, where a deep degree of anæsthesia was required, he was unable to produce it and the surgeon asked him to get the patient more deeply under, but he (Dr Buxton) had failed That perhaps was owing to want of skill and he was quite ready to be told that he should have tried longer But in an ordinary hospital this was impossible unless a higher percentage could be obtained Short of that he could speak in the highest terms of the apparatus It was necessary to be careful of the position of the bottle, but there was no difficulty in warming it with the hand Up to the present he had had no unpleasant experiences, but on that point it was necessary to say a few words It would be most deplorable if the public thought, and a patient could say, "Give me a 2 per cent. and there will be no danger" In giving chloroform at any percentage there was a certain risk, in fact, although the danger might be lessened by using a low percentage, yet there was no absolute immunity The real action of chloroform was not yet known There were so many factors to consider that mere percentage dosing was not sufficient to insure safety, for instance, inspiration might be normal but expiration insufficient, and thus the chloroform would accumulate in the system and the nervous tissues become more and more soaked, there were so many other factors that it was beyond the power of man to say that salvation was in any percentage

Mr HARVEY HILLIARD observed that he had used the apparatus and had been very much struck with the quiet way in which anæsthesia had been induced, beginning with 0 25 per cent and working up to 1 per cent., which had been sufficient to produce anæsthesia but not to a sufficiently deep degree and he had had to push on in his first case (which had been the worst and was an abdominal section) to 2 per cent, but this was insufficient to abolish all rigidity He was working in a temperature of 75° F but without the specific gravity bulbs, and to try to get a deeper anæsthesia he warmed the bottle, which had only been half filled, with the hand. A little later, however, the boy showing signs of vomiting there was no time to try to deepen the anæsthesia with this apparatus, so he changed to a Skinner, returning to Mr Harcourt's apparatus when things were smoother but with the same result He agreed with Dr Buxton that 2 per cent. was not sufficient to produce a sufficiently deep anæsthesia in all cases, especially in some abdominal operations Mr Hilliard thought at first that his difficulty was due to the face-piece not fitting, but made sure that it was, for the valves were acting perfectly Mr Hilliard also mentioned other cases nearly similar Induction was perfect in all his cases, four sixths of which were abdominal, but 2 per cent. anæsthesia was not sufficient to deepen the anæsthesia to dilatation of the pupil and in one case without warming the bottle he could not abolish the corneal reflex One most satisfactory case was one in which craniotomy was performed, anæsthesia was induced and maintained at 1 5 per cent. The patient remained under satisfactorily except when the head was being crushed, then, however, there was a little straining and the chloroform bottle had to be filled up to three quarters and the hand placed round it, this was sufficient to deepen the anæsthesia. The temperature of the room was 60° Acting on his experience with the method Mr Hilliard said that he now always filled the bottle three quarters full

In reply to a question by Mr NORTON, Mr HILLIARD said that induction of anæsthesia took about eight minutes, in his first case it took from eight to ten minutes He considered that a slow induction gradually working up from a low percentage was best, the induction then being most quiet

Dr S H BELFRAGE thought that possibly the face piece and the apparatus might be connected by means of a flexible tube. This would leave the anæsthetist's hands more free.

Dr G EASTES wished to know how much liquid chloroform was required to produce a given amount of vapour

Mr HARCOURT replied that one volume of liquid chloroform gave 300 volumes at an ordinary temperature and pressure

Dr EASTES remarked that he constantly used Clover's regulating chloroform inhaler and found it the best apparatus which he had ever used The great advantage was that the measured maximum percentage of vapour was all measured out beforehand and this, he thought, was better than making their own percentages as the case proceeded

Dr W J MCCARDIE being asked for his experience when experimented on with Mr Harcourt's inhaler answered that it was short but pleasant. At first Dr Buxton had given him 0 5 per cent for five minutes which had had no effect. After an interval of five minutes he had received 1 per cent, this was very much stronger, so much so that he had lost consciousness in about one and a half minutes. He believed anæsthesia was so deep that the conjunctival reflex was abolished. The anæsthesia produced was sufficient for such tests as pin pricks upon his hands, but he did not know if it would be deep enough for abdominal operations 2 per cent., he considered, ought to be deep enough for all ordinary operations and for average anæsthesia. But he thought for experts that it would be a great advantage if Mr Harcourt's apparatus could be made to give up to, say 4 per cent, but for the ordinary medical man it was perhaps an advantage to have the low percentage beyond which he could not go

Mr HARCOURT in answer to the various questions and suggestions to which his paper had given rise, said with regard to that about one hand being always employed in raising the temperature his experience with the bottle was small He had seen an operation by Sir Victor Horsley which lasted a full hour The assistant seemed to have one hand free the whole time, the other feeling the pulse or being round the bottle of chloroform. He considered that in the high temperature of a theatre an occasional application of the hand ought to be enough Certainly something more simple than applying the hand was desirable if it could be found Concerning the using of more than 2 per cent he had carefully watched the stop-cock at an operation The 2 per cent. limit was never reached. He thought that as the common way of giving chloroform was with a loosely fitting mask possibly Mr Hilliard's difficulty to obtain in all cases a sufficiently deep anæsthesia was due to his not fitting the face piece with sufficient accuracy, although the valves might still be working If only two-thirds of the whole inspiration passed through the apparatus and one-third round the face piece that would make a very considerable difference in the dose. It was quite easy to increase the percentage of vapour by increasing the size of the bottle. If the cross-section of the bottle were doubled it would give double the percentage of chloroform vapour In reply to the suggestions of an india-rubber tube that would be easy, but he was advised to give it up on the grounds that the air in the tube would be re-breathed and that it was best to make the distance as short as possible. There would be no difficulty if preferred to have it made so that it stood on a stand, yet these tubes were liable to kink.

A vote of thanks, proposed by the PRESIDENT and seconded by Mr EASTES was then passed.

Mr. W G COPESTAKE then showed his Apparatus for administering Ether, Chloroform, or Mixture, and said that the apparatus remained practically the same as that which he described in the year 1900, the only alteration being the substitution of a glass jar, to contain hot water to heat the ether when by evaporation it got too cold, for the less satisfactory method of warming it by the anæsthetist's hand He also read notes of 69 cases he had anæsthetised with the apparatus with very satisfactory results. He claimed for the apparatus that the amount of sickness was less than when ether was given in the ordinary way, that the discomfort was less to the patient, and that the consumption of ether was less

The PRESIDENT asked if gas were given as a preliminary to the ether and how long it took to induce anæsthesia

Mr. COPESTAKE replied that gas was not given and that induction took from eight to ten minutes.

The PRESIDENT remarked that in London they were always in a hurry and in hospital practice could not spare ten minutes over the induction of each case

Mr HILLIARD said that he had seen Mr. Copestake use his apparatus that afternoon in one case and that the result was entirely satisfactory although induction was long

---

CHELSEA CLINICAL SOCIETY

Discussion on Diabetic and Non-diabetic Glycosuria

THE annual clinical debate of this society was held at the Jenner Institute of Preventive Medicine, Chelsea Gardens S.W, on March 10th. Dr C C GIBBES, the President, being in the chair.

The debate was opened by Dr W HALE WHITE, whose remarks will be found in full in THE LANCET of March 14th p. 714

Dr F W PAVY said that they had all listened with much interest to Dr Hale White's able opening address but different minds approached a subject from different directions, and his (Dr Pavy's) mind had been concentrated upon the distinction between diabetic glycosuria and non diabetic glycosuria. The first point in drawing a distinction between the diabetic and non diabetic glycosuria was to decide what constituted diabetic glycosuria The broad facts before them were that a diabetic subject differed from a healthy subject in the following respects the healthy subject took carbohydrate food and all he knew after taking this food was the benefit which he had derived from it. The food did not show itself as sugar in the urine, nor did it increase the amount of sugar in the blood The amount of sugar in the blood remained fairly constant no matter what the diet, taking an ordinary diet, might be, and the urine reflected the character of the blood. There was a certain amount of sugar naturally existing in the blood and there was a certain amount of sugar naturally existing in the urine. If the amount of sugar in the blood were increased the amount of sugar in the urine immediately increased. They were all in reality glycosurics, as were also the lower animals, but only glycosurics to quite a small extent. He did not rely upon the copper test. By means of the fermentation test the presence of sugar was susceptible of demonstration He thought that it might be looked upon as a demonstrable fact that sugar was present in healthy urine so that diabetes only varied as regarded degree In the healthy subject carbohydrate food was taken and did not increase the amount of sugar in the blood, so that the sugar in the urine came from that constant sugar which was present in the blood In an ordinary case of diabetes in proportion as carbohydrate food was given so was sugar present in the urine, the carbohydrate of the food being no longer dealt with as it was in the healthy subject In the healthy subject it was in part converted into fat and in part synthesised into molecules which could traverse the blood without escaping with the urine. Sugar consisted of such small molecules that as it was passing through the glomeruli of the kidney it filtered away in the same manner as water, as urea, or as saline matter Sugar that reached the blood could not do otherwise than pass off with the urine, and thus if sugar reached the blood it would be sure to reach the urine. By the process of assimilation the sugar was built up into larger sized molecules and glycogen was nothing more than an extensive aggregation of sugar molecules with at the same time a certain amount of dehydration, or the sugar might be incorporated into proteid and in the proteid molecule it could circulate freely without any danger of escaping with the urine There was no doubt that the sugar which was derived from the food passed by the process of assimilation into large sized molecules which could circulate through the body without running off with the urine as the smaller sized sugar molecule did. In diabetes there was a want of this assimilative power—the power no longer existed of putting the carbohydrate of the food into a form capable of being retained in the body, if taken with the food it reached the blood as sugar and then ran off through the glomeruli of the kidney In what was called the "alimentary" form of diabetes that was what occurred. Sugar might also reach the urine from the breaking down of proteid which had been formed previously with the concurrence of sugar, and this was associated with what he had called the "composite" form of the disease. Thus they might have sugar in the diabetic from two sources—from the non assimilated carbohydrates of the food and from the breaking down of the proteid matter The former condition might exist alone—the "alimentary" form of the disease, the latter however, did not exist unassociated with the former; hence the term "composite" applied to it. As in all cases of diabetes the former condition existed, the disease might be defined as "a more or less persistent defective assimilative power over carbohydrate of food resulting in glycosuria." If they approached the consideration of diabetic and non diabetic glycosuria from that standpoint they could see into which category a particular case should fall It might first of all be said that apart from disease anyone might be rendered glycosuric. In ordinary circumstances a person did not get sugar in his urine from his food but under an undue ingestion of sugar he might do so This class of case would not fall into the category of diabetes, because it did not involve defect of assimilative power The sugar in the urine resulted not from a defective assimilative power but from carbohydrate having been taken to a sufficient extent to outstrip, as it were, the natural power to deal with it In relation to diabetic glycosuria the widest variation was noticeable in assimilative power In some instances there might be only so slight a diminution of the power that there was no sugar in the urine under an ordinary mode of feeding There was sugar in the urine, it was true, after taking an amount of carbohydrates that could be taken by a perfectly healthy person without passing sugar, but there was not much distinction and in differentiating cases of this kind testing with food required to be had recourse to They were borderline cases Sometimes there was sugar discoverable in the urine, at other times not, and the condition was most puzzling to medical practitioners. These cases depended upon the amount of carbohydrate which happened to have been previously taken. Were these cases to be considered as of diabetic or non-diabetic glycosuria? Testing with food would decide the point. If such a person were given a large amount of carbohydrate and there was any weakness of assimilative power existing the evidence of that weakness would be brought out. Some time ago an individual in connexion with whose condition different opinions had been given was sent to him (Dr Pavy) by an insurance office to be examined The urine which he passed for examination a few hours after ordinary food for breakfast, including bread and toast, was found to be free from sugar To know whether he really was a diabetic or not he was subjected to a test meal consisting of bread-and butter and marmalade and this was accompanied by a glass of sherry In a couple of hours time the urine which the patient passed was loaded with sugar He had no hesitation in saying that that person was the subject of a mild form of diabetes In reference to mild glycosuria a case was quoted which had extended over 30 years and he thought it was an interesting circumstance that the son of this patient a boy nine years of age had been under Dr S J Gee's care and that Dr Gee had found sugar in his urine Dr Pavy considered that cases of this kind fell into the category of diabetes, but of a very mild form. Experience showed that the condition of these patients with respect to assimilative power might vary at different times They must not look upon the condition of a patient as stereotyped or absolutely fixed, and a condition that existed at one time might be less favourable to the assimilation of carbohydrates than at another time. A striking case of this kind fell under his observation a few years ago The patient had been for some years a comparatively mild glycosuric—if she took much starchy food she had sugar in her urine. But with moderate restriction she could keep her urine free from sugar She became the subject of a severe attack of pneumonia, and through the illness sugar was, apart from food to account for it, persistently present in the urine and the condition passed on into the "composite" type of diabetes There were diacetic acid and oxybutyric acid present in the urine and it seemed at one time as if coma were threatening The patient recovered from her pneumonia and had since reverted to her original condition of mild glycosuria without the acetone series of products Dr Hale White had drawn attention to a case showing the effect of starchy food giving rise to the elimination of a larger amount of sugar than could be derived from the starchy food taken. This result was in harmony with what might be observed in the progress of any ordinary case A person became the subject of diabetes and they would assume that its existence was not known, he went on for some time and progressively found that he was growing worse Supposing it to have been a case which had begun mildly and then gradually advanced the train of phenomena might stand as follows. At the mild beginning the patient could take a considerable amount of carbohydrate without passing sugar, but as time went on he began to pass sugar and then passed more and more The case became gradually more aggravated—in other words, the assimilative power became more and more diminished—and the amount of carbohydrate which would only throw a little sugar into the urine at the commencement would later be found to lead to the passage of a large amount. Exactly the reverse occurred under proper treatment. A patient presented himself who was the subject of an amenable form of diabetes and he was put upon the appropriate treatment Perhaps under the restricted diet the sugar might not at first be susceptible of complete removal from the urine, but after a lapse of time which cannot be foretold—in one case it might be two or three months, and in another it might not be for a year or two—indications would set in of a returning assimilative power The indications were these as long as the restricted diet was required from want of assimilative power the patient maintained his weight and his strength and felt in himself perfectly well. But with the return of assimilative power he complained of an epigastric sinking He also felt weak and lost weight This patient must then be given a small quantity of starchy food, beginning with three ounces of wheaten bread per diem in one ounce portions at each of the three principal meals It would be found that the allowance of bread would not throw sugar into the urine, and the patient would feel relieved at once and his weight would increase By and bye there would be a return of the former symptoms, and a drop in weight and so on, which must be met by an increase in the amount of carbohydrate given, and in this way he (Dr Pavy) had frequently advanced it up to seven, eight, nine, and sometimes to 12 ounces of bread a day without bringing back the sugar The starchy food which was thus taken was properly assimilated and went to the good of the system instead of running off as waste material with the urine This was absolute proof that the condition of the system had changed, there was a return of the assimilative power over carbohydrates to a significant extent As a rule, these cases did not regain their complete power Some were able to take ordinary diet without passing sugar upon it, but the usual event was that there was a return of assimilative power to a certain point which varied in different cases. The inference to be drawn from what he had said was that the presence of only a slight amount of sugar had nothing to do with the classification of glycosuria into diabetic and non diabetic groups. He would speak of non-diabetic glycosuria as independent of the question of carbohydrate assimilation, it arose from conditions unconnected with the character of the food Obstruction of the breathing, for instance, as in asphyxia, might throw sugar into the urine and give rise to glycosuria, but this did not fall within the definition which he had just given of diabetic glycosuria. In whooping-cough there might be sugar in the urine as a result of violent paroxysms of coughing In coma and in convulsions there might be sugar in the urine. An anæsthetic might throw a certain amount of sugar into the urine. There might be sugar in the urine in connexion with lactation and as a result of poisoning by carbon monoxide. All these conditions he classified as non diabetic glycosuria. Cases now and then presented themselves where sugar was met with in the urine simply once and although the patient would be watched for a considerable time no sugar would be again found This sort of case he would not put into the diabetic category As an instance of this kind of case Dr Pavy related that of a man who desired to insure his life and who on several separate occasions after partaking of a meat lunch with lager beer passed sugar in his urine, while all urine passed at other times was quite free from sugar It looked as if the sugar had been put into the urine by the lager beer In Germany lager beer glycosuria was recognised

Dr **ROBERT SAUNDBY** said that he regarded glycosuria in the following way The normal man was capable of assimilating a certain amount of carbohydrate, but, as Dr Pavy had said, there was no fixed quantity Some men tended to store up a great deal of carbohydrate which they ingested in the form of fat, others burnt it off This ingestion of carbohydrates was very much more vigorous in young people than it was in those who were getting older, what might be called the sugar destroying or sugar burning function of the body diminished as time went on and after middle age it certainly diminished considerably That was why it was a fairly common thing to meet with glycosuria in elderly people A good deal of the glycosuria of elderly people was simply alimentary—that was to say, as people got more into years their appetites did not get less, they stayed longer at table and did not take so much exercise, and were more liable to take an excessive quantity of carbohydrate food and therefore to have a surplus which passed off in the urine. Dr Pavy had said that diabetic glycosuria was a glycosuria in which assimilation failed and that non diabetic glycosuria was that in which assimilation was not at fault. He (Dr Saundby) was not able to accept that definition He suggested what seemed to him a more practical and more clinical view of the subject He thought that where they knew the cause and could possibly remove it they should not call that diabetic glycosuria. Where they did not know the cause and where it persisted it was probably diabetes. As an example nothing had been more strongly impressed on him of late years than the truth of what was not generally admitted and had been denied by many great authorities on diabetes—namely, the influence of alcohol in producing glycosuria In a case that had been quoted by Dr Pavy it might have been due to the carbohydrates in the lager beer, but he had seen it produced by whisky many times Dr R. T Williamson of Manchester, who had written on diabetes, was strongly convinced of the effect of alcohol in producing glycosuria. There were many other causes of temporary glycosuria besides alcohol, some of which had been touched upon by Dr Pavy Glycosuria in association with boils and carbuncles was often seen, also in connexion with various surgical wounds and infections. People did not react in the same way to all forms of carbohydrates, and not only did people differ very much in their capacity for assimilating carbohydrates but the same man would react differently to different forms of carbohydrates He had found that many diabetics could take from one to one and a half ounces of lævulose without producing any increase in the amount of sugar excreted. There were other things of more practical importance Lævulose was rather expensive and did not help very much in the diet. Milk was very important in this respect, it was a valuable and popular article of diet, and it was a great thing to know that most diabetics could assimilate definite small quantities of milk without producing any increase in the quantity of sugar excreted. His plan in treating diabetes was invariably to watch the amount of sugar excreted. He collected the whole of the urine excreted in the 24 hours and estimated the whole quantity of sugar passed He was thus able to know the quantity of sugar excreted in a day and could easily see whether an additional half pint of milk made any notable difference in the excretion of sugar The utility of potatoes in the treatment of diabetes had been pointed out. Potatoes contained a very small amount of starch, whereas bread contained about 50 per cent. of starch, potatoes only contained from 15 to 20 per cent of starch. A man might be given a potato weighing six ounces and a large potato like that enabled a man to get through his meal without troubling about toast and bread. Supposing that instead of this potato they gave their patients one ounce of toast, that would be equivalent to 300 or 400 grains of starch. Potatoes did not contain so much starch as gluten bread Dr Saundby then related the histories of three cases which were, he considered, an encouragement to try the effect of potatoes as a substitute for bread. The points which he particularly wished to impress upon the meeting were, first of all, that there were many cases of glycosuria which were not properly diabetic and in which a cause could be found if looked for one of the commonest of them met with in practice being alcohol. The second point was that people varied very much in their capacity for assimilating carbohydrates and that if they wished to treat patients successfully they must calculate the total output of sugar and not be content with mere percentages They must also calculate the total amount of carbohydrates which they were putting into the body and see how these carbohydrates were eliminated The sugar which was eliminated was not wholly derived from the carbohydrates of the food, sugar was also formed from the proteids Another important practical point was to weigh the patients who were the subjects of treatment for diabetes

Dr J ROSE BRADFORD said that the relation of glycosuria to diabetes had always been a point of considerable interest and a debate on diabetic and non diabetic glycosuria would suggest that it was now recognised that sugar might not only be present in small quantities in health but that it might exist in the urine as a result of other morbid processes than those described as diabetic. Glycosuria of non diabetic origin should be carefully distinguished from the mere presence of reducing substances other than sugar in the urine. Some of these reducing substances were really normal constituents of the urine as, for instance, uric acid, creatinin, and glycuronic acid These might give a spurious sugar reduction either owing to their being present in increased quantity or as was not uncommonly the case, simply depending on the urine being rather more concentrated than usual and this, for instance, was notably the case with reference to uric acid In other instances these bodies were present in increased amount owing to morbid processes, as might be the case with uric acid and creatinin and possibly glycuronic acid, all of which, it would seem, might be increased in considerable amount in a number of wasting and general diseases Further, they might be present in largely increased amount as the result of the ingestion of certain substances, and more especially some drugs. This was notably the case with reference to glycuronic acid which might be present in greatly increased amount after the administration of camphor, chloral, or carbolic acid Although these substances were of great practical importance owing to the not infrequent error of diagnosing glycosuria from their presence the further consideration of them did not fall within the limits of a debate on glycosuria, inasmuch as sugar was not really present as could be readily observed as a result of the fermentation and other suitable tests In the next place, other sugars, as, for example lactose and pentose—though especially the former—might be present in quite considerable quantities as, for instance, in the urine of suckling women, and although that technically fell within the definition of the non-diabetic glycosuria the term was generally used as synonymous with the presence of dextrose in the urine. The first question that presented itself if the term "glycosuria" was limited to the presence of dextrose in the urine was really whether there was such a condition as non diabetic glycosuria when they remembered that many of the conditions so described were now capable of explanation with their fuller knowledge as due to the presence of other reducing substances or other sugars in the urine. The fact that sugar was present in small quantity in health was undoubtedly suggestive of the possibility of the occurrence of non-diabetic glycosuria. The conditions, however, in which sugar was undoubtedly present in appreciable amount apart from the presence of diabetes were at any rate not numerous. Instances were occasionally seen of the transitory presence of considerable quantities of sugar in the urine supposed to be dependent on the ingestion of large quantities of carbohydrate material and ceasing not only when the carbohydrate material in the food was cut off, but also when it was only diminished to reasonable proportions. Still, such cases as those were not very far removed from the slighter forms of genuine alimentary diabetes, although possibly they might not lead to the serious developments that occurred in genuine and confirmed diabetes. In very exceptional instances sugar apparently might appear in the urine in quite appreciable quantity as a result either of severe exercise or fatigue. He had seen one such instance in the case of a young man apparently healthy who after a long and fatiguing walk excreted an appreciable amount of sugar in the urine, but where the condition was quite transitory and led to no ill effects. Sugar might appear in the urine after the administration of morphia and possibly after prolonged anæsthesia, and in the latter instance at any rate acetone was not infrequently present But when those various and exceptional cases were put aside there only remained injuries of the head and various intracranial diseases, especially in the vicinity of the medulla, which all would agree to as undoubted causes of non diabetic glycosuria Glycosuria was not uncommon even as an accompaniment of certain forms of cerebral hæmorrhage and so much was that the case that some writers had given a totally different interpretation to these cases and had looked on the hemiplegia and the vascular lesion as the result of diabetes That view, however, was improbable, as the presence of the sugar was often directly related to the acute cerebral lesion and was transitory, and these cases were really strictly comparable to the experimental glycosuria produced by Bernard with his celebrated diabetic puncture. That, however, was a misnomer, as the condition produced by Bernard was really a glycosuria, transitory and apparently dependent on the so-called irritation produced by the medullary hæmorrhage, and was really in no way comparable to the disease spoken of as diabetes It would seem that non diabetic glycosuria might therefore be correlated not only with injuries and perhaps functional disturbance of the central nervous system but also with the excessive ingestion of carbohydrates in certain persons, and probably also as a result of the action of certain toxic substances, and it might, perhaps, be occasionally associated with the results of muscular fatigue Glycosuria might not only be of mixed origin when it was of non-diabetic origin, but even when due to diabetes it was probable that many distinct and separate forms would be recognised in the future, if not at present. Before classifying the various forms of diabetes attention must be drawn to the very remarkable fact that the glycosuria might not only diminish but might even disappear during the course of diabetes, not only when the malady was undergoing improvement, but when fatal complications were present Thus it was well known that glycosuria might disappear either before, or synchronously with, or after, the onset of coma and that in some cases the urine might remain free from sugar for many days before the onset of the coma. Further, the development of inflammatory complications in the course of diabetes was extraordinarily apt to be accompanied by a diminution, if not a disappearance, of the sugar and that quite apart from the development of coma. It would seem, therefore, in the metabolic processes occurring in a diabetic patient where pyrexia was present that the sugar could be oxidised In some complications not accompanied by coma or fever, as, for instance, Bright's disease occurring during the course of diabetes, sugar might also undergo diminution or even disappear Thus, although the presence of glycosuria was so intimately associated with diabetes, yet that disease might exist and be fatal where no sugar was present The undoubtedly mixed group of cases described under the single term "diabetes" might be divided up in a great variety of ways, by classification based either on the clinical symptoms or on the character of the urine excreted Thus there were some cases of diabetes in which the quantity of urine was not notably increased and therefore the quantity of sugar excreted was necessarily moderate and the presence of the sugar was almost the only abnormality in the urine. There were others where the quantity of urine was enormously increased, the amount of sugar correspondingly large, and where in addition, other bodies—acetone diacetic acid, oxybutyric acid &c.—were present. That this distinction was a really vital one was shown by the different course the malady ran in the two instances and the greater beneficial influence of treatment in the first series In the more formidable cases the quantity of nitrogen excreted was very large, associated with the greatly increased tissue waste that was present. Another classification of diabetes might be based on the different age of the patients affected and no doubt, speaking generally, the disease was apt to run somewhat different courses in children, in adults, and in the elderly But before their knowledge of diabetes could be considered thoroughly satisfactory it would probably be necessary to have a classification based on pathological facts rather than on the natural history of the morbid process. From a consideration of diabetes itself, and especially from the results of physiological inquiry, it would seem that some five varieties of diabetic glycosuria might perhaps be described, although in the present state of their knowledge it was not possible to separate all of them clinically First, there was evidence in favour of the existence of glycosuria as a result of disturbed function of the absorptive and other mechanisms of the alimentary canal so that a definite alimentary variety of glycosuria, characterised mainly by the intimate relationship of the glycosuria with the carbohydrates ingested, might be recognised Secondly, most authorities would admit that glycosuria might have a hepatic origin dependent perhaps on the liver not arresting the glycogen brought to it, and possibly in other instances dependent on the liver forming too much sugar Thirdly, a pancreatic diabetes might be admitted to exist, both from the experimental standpoint and from that of human morbid anatomy Fourthly, it was probable that a renal glycosuria existed, especially in the light of experimental results obtained with phloridzin, as it would seem that this glucoside caused glycosuria by an action on the renal cells That opened up the whole question of the relationship of morbid processes in the kidney to diabetes and might place in a new light the well known fact that in certain cases of diabetes the kidney was greatly hypertrophied This, in his opinion, could not be associated simply with the increase of urine excreted, as renal hypertrophy was by no means an invariable accompaniment of diabetes Further, the fact that glycosuria might disappear in cases of diabetes when an acute renal complication such as Bright's disease supervened might also receive a new explanation in the light of these phloridzin results Fifthly, it had been suggested, and should at any rate be admitted as possible, that a diabetic glycosuria might perhaps arise as a result of a primary disintegration of the tissues. In this enumeration of the possible varieties of diabetes the nervous system had been omitted, as although the fact that the nervous system played a part in the production of the disease must be admitted on clinical grounds there was only evidence from the experimental standpoint that lesions of the nervous system produced glycosuria rather than diabetes.

EDINBURGH MEDICO CHIRURGICAL SOCIETY

Exhibition of Cases and Specimens —Gastric Hyperacidity (Hyperchlorhydria) —Disinfection of the Hands

THE seventh ordinary meeting of this society was held on March 4th, Dr C E UNDERHILL (in the absence of Sir THOMAS R FRASER) being in the chair

Dr D CHALMERS WATSON showed a case of Verrucæ Planæ Juveniles. The patient, a boy, aged 13 years, had suffered from the eruption on the face for eight months. A large warty growth (mother wart) had existed on the leg for about two years and several common warts (verrucæ vulgares) had been present on the hands for a year The treatment consisted in the administration of large doses of castor oil given twice a week for the first two weeks and thereafter once a week. At the end of three weeks the eruption on the face had disappeared and that on the hands had improved. Three weeks later the warts on the limb had undergone no change Photographs were shown illustrating the original condition.

Dr F D BOYD demonstrated 1 A case of Localised Syphilitic Meningo-myelitis in a man who had contracted syphilis 20 years ago There were complete anæsthesia of one half of the penis and scrotum and an anæsthetic area on the back of the right thigh and leg, the anal reflex was gone but the bladder was unaffected 2. A case of Ophthalmoplegia. The patient suffered from locomotor ataxia and a year previously had perforating ulcers on both feet. The whole of the muscles of the left eye were paralysed, the pupils were dilated on both sides and nystagmus was present. There were slight paralysis of the tongue and soft palate and complete paralysis of the abductors of the left vocal cord as well as slight paralysis of those of the right side.

Dr G A. GIBSON exhibited 1 A child with combined Obstruction and Incompetence of both Aortic and Pulmonary Orifices There was a history of acute rheumatism and the pain complained of resembled that of angina pectoris The single systolic murmur was conducted over a large area of the chest, one of the diastolic murmurs was musical in character and widely conducted, while the other was only heard over an area of about one and a half square inches 2. A man, aged 22 years, with Raynaud's disease showing interesting features The veins of the leg were like pieces of whip cord and that their condition was due to spasm was shown by the fact that they resumed their normal character under a vapour bath

Dr JOHN THOMSON demonstrated a case of Spasmodic Stricture of the Œsophagus in a boy, nine years of age There was a history of inability to swallow solid or semi solid food during all his life, there were recurrent causeless attacks of vomiting The vomited matters were unchanged because the food did not reach the stomach The œsophagus could accommodate about four ounces He rapidly regained weight when the attacks of vomiting ceased The obstruction was situated about nine and a half inches from the teeth and had given origin to a dilatation also

Mr H ALEXIS THOMSON showed —1. A case of Dupuytren's Contraction of the Palmar Fascia. One hand was treated by Adams's method and the other by excision, and the result was in favour of the former method 2. A case of Infantile Paralysis of the Lower Extremity treated by arthrodesis of the knee and Pirogoff's amputation at the ankle eight years ago The patient could now use the limb fairly well for walking

Mr H. J STILES exhibited —1 A child, aged two years, showing the first stage in the treatment of Double Congenital Dislocation of the Hip The reduction was effected ten days previously when the limb was abducted at right angles, this abduction was gradually reduced, plaster being applied each time, 2. An infant after Excision of Suboccipital Meningocele, complicated with Hydrocephalus, though no permanent improvement was expected.

Mr R A LUNDIE showed a child whose Metacarpal Bone of the Ring Finger of the Right Hand was much shorter than its fellows owing to an early synostosis of the epiphysis and diaphysis

Dr WILLIAM RUSSELL read a paper on Gastric Hyperacidity (Hyperchlorhydria), its Nature and its Relation to Dyspepsia and Dilatation. He said that not many years since it was generally taught and universally believed that gastric hyperacidity was due to the presence of organic acids, the products of the fermentation of food in the stomach, the fermentation being caused by organisms. This widely accepted view was probably the result of observations on the contents of the stomach in pyloric obstruction. The inference that gastric contents underwent fermentation whenever unduly retained came to be applied to all, or nearly all, gastric disturbances In recent years, with increased knowledge of digestive processes, it had become evident that there was a gastric hyperacidity due, not to the fermentation of food stuffs in the stomach, but to a true excess in the amount of the special acid normally secreted by the organ. The term hyperchlorhydria or hyperchylia had been applied to this condition. This hyperchloric acid excess was, in Dr Russell's experience, a much more common cause of dyspepsia and ultimately of gastric dilatation than was at present recognised It was the primary fault in many cases which were classed as nervous neurotic, or irritation indigestion and not infrequently it stood in the same relation to cases named gastric catarrh or gastric dilatation. Of the cases of dyspepsia which he had seen at the Royal Infirmary he would place about 25 per cent. as due to hyperchlorhydria and of cases seen privately even a higher proportion was met with As regards elucidation of the symptoms he began by inquiring how the patient felt on getting up in the morning, then the hour of breakfast and the nature of the meal, how he felt after breakfast and if any pain, discomfort, or other symptoms were experienced during the forenoon and the hour at which these came on, how long they lasted, and whether they continued up to the time of taking the midday meal. If symptoms continued up to this meal he ascertained the effect which the midday meal had upon them, whether they were at once aggravated, materially relieved, or entirely d, at least for the time. He then inquired as to the ition of the midday meal and as to the afternoon ms and so on until bed time, if necessary Exact dge of symptoms was of the greatest value in helping s the determination of the part of the digestive which was at fault. The history thus obtained ten so characteristic as to warrant a diagnosis of hlorhydria without chemical examination. Such a stic history might be as follows The patient felt quite the morning and had no discomfort until during enoon, he could often state the hour at which dis- t or pain began—from one to two and a half hours reakfast—the time varying in different patients, or n the same patient The pain after lasting an r two might pass off, to reappear an hour or after the midday meal. If the pain continued up to the time of taking this meal the par of it removed the pain for a time, the period ef varying from half an hour to an hour The n of the interval of comfort depended upon the y of the condition and the composition of the midday This sequence of events—meals, intervals of relief, re- e of pain or discomfort—might be maintained through- rest of the day If the last meal were taken near e the patient might be wakened from sleep by pain or ymptoms which might prevent sleep for an hour or he pain or discomfort varied within wide limits—severe te and described as grinding gnawing, boring, g or giving sensations of dragging, oppression and ion. The pain was usually referred to the epigastrium, o might be in the back near the spine, behind either r blade, or most acute in the position of the pylorus or e liver behind The measure and site of the pain ed upon the duration and severity of the condition han on any neuropathic tendency in the individual ther department was so much attributed to disordered urbed innervation as in gastric disorders and the ration of this factor tended to relegate to a subsidiary he part taken by diet and altered secretion in pro- the symptoms Symptoms were referred to as *nervous* he nerve condition were the primary factor when it t the sensory index of disordered chemistry Epi- tenderness might be present, but as a rule only in cases of considerable duration. The tenderness was uperficial and was readily relieved by friction of the Other symptoms referred directly to the stomach were t distension, gaseous eructations heartburn and acid ions The eructation of gas or of a small quantity of aterial gave relief often very marked though tem The bowels were constipated or the evacuations were lete. In severe cases there was sometimes great l and mental misery, coming on or attaining its worst the other symptoms were at their height. The most ent of these was a sense of physical and mental ex n, languor, weariness, and weight in the lower limbs ability to apply mind or body to any work. Another m had been well described by Sir William Roberts as ysmal pyrosis," and he regarded it as an "abortive complete act of vomiting' Dr Russell thought, how- hat this latter was a pyloric phenomenon and occurred ly when there was a surplus of acid in the stomach. plain the symptoms a precise knowledge and clear hension of the gastric processes of digestion were ry The three chemical phenomena of starch on, arrest of starch digestion, and proteid digestion those upon which the unconscious comfort or onscious discomfort of digestion primarily de l. When the chemical equilibrium and balance this period were maintained the stomach worked t obtruding its existence on its owner's notice The ect relation" between the amount of proteid and the amount of gastric secretion had to be d. No more gastric juice ought to be poured an could be taken up by the proteid. When this atisfied the secretion of gastric juice ought to cease, pened in normal conditions If this arrest of secretion t occur the equilibrium was upset and the resulting bation depended upon the measure of the excess. The t in the secretion which was the disturbing factor was ydrochloric acid and not the special enzyme. The of this hyperchlorhydria upon the gastric contents was orthy The proteid elements of the food were digested exceptional rapidity and it might be thought that the food substance, especially the finely divided starch food as bread and oatmeal porridge, would readily pass out of the stomach with the dissolved proteids, but this did not happen A considerable portion of unaltered starch was really kept back and retained in the stomach, as Dr Russell had frequently found. The effect of this retained and unaltered starch was to keep up the gastric secretion, while it presented no constituent with which it could combine This undigested starch was ultimately passed on into the duodenum, but only after much local and often general discomfort, though it might also be rejected finally by vomiting A considerable amount of the fat of milk might be retained in the same way in the stomach and Dr Russell had noted this on several occasions when the casein of the milk had disappeared and this even in the case of peptonised milk. In such cases the fat of the milk was diffused through the acid fluid removed from the stomach, partly floating upon it as if it were a mass of mucus This fat also kept up the secretion and presenting no element with which the hydrochloric acid could combine the discomforts of hyperchlorhydria emerged. A third important factor in determining the severity of the symptoms was the kind of proteid food taken The general law was that the less stimulating and the more easily digested proteids caused less discomfort than did those of a contrary character In all three conditions there was the common factor of continued gastric secretion—continued beyond what was required and so beyond what could be utilised. This continued secretion, when examined, was found to contain a high percentage of acidity, much acid being free. At this stage the stomach contents might only measure from one to a few ounces of very acrid material, mainly fluid containing starch, some milk fat, and shreds of undigested material, according to the kind of food partaken of. The main residue in ordinary cases was starch At this period the gastric symptoms were very severe and on withdrawing the contents the smallness of the quantity was remarkable. Why a residuum of finely divided, although undigested, starch should remain in the stomach when other material had passed the pylorus was difficult to explain. The results of clinical observation showed Dr Russell that the unaltered starch was delayed in the stomach and that it was so even when broken up and when digested proteids had escaped Being thus delayed it continued to stimulate the gastric secretion and there being no more proteid with which to combine the secretion accumulated and led to hyperacidity That this hyperacidity was due to a true hypersecretion was proved by the great peptonising power of the filtered contents. When the residuum in the stomach became hyperacid its continued retention was due to the spasm of the pyloric sphincter induced by the acidity As regards etiology it was found that the affection was usually classed under the gastric neuroses—gastrodynia, irritation &c.—though the writers were not always clear as to the meaning of the terms, whether the pain and discomfort were merely subjective nervous phenomena or whether an assumed neurotic diathesis determined an increased secretion of hydrochloric acid. Dr Russell's theory was that the nervous mechanism was the part of the system which was primarily deranged. He thought that this conception was erroneous and full of evil consequences. All deviations of secretion from an average standard all increases of secretion, all modifications of chemico-vital reaction were not explained or defined by the word "neurotic' and it was time that this word and the idea were relegated to a less prominent place when considering disturbances of gastric function. As a result of his chemical experience and the examination of gastric contents he would submit that certain persons were prone to secrete overmuch gastric juice and that possibly the constituent which was primarily at fault was the hydrochloric acid. He had been impressed with the occurence of severe hyperacidity in some gouty and rheumatic subjects and in some persons as a consequence of a diet rich in nitrogenous substances. There was little doubt that to their list of constitutional conditions the acid dyscrasia might be added To regard the intense misery of some hyperchlorhydria as a mere neurosis was unjust to the victims. Apart from this however, he held that the merely neurotic view was disproved by the following phenomena which he had often observed the immediate relief obtained by removing an ounce or two of acrid stomach residuum, a like relief obtained by neutralising the acid by means of alkalies and the measure of relief obtained by mere dilution. That the over secretion was more a chemical and a diathetic error than a neurosis was further supported by the experience that the mechanical removal of the hyperacid residuum in severe cases more promptly overcame the attack than any dietetic or medicinal measure, as if the withdrawal of the acid removed an overflow which otherwise was difficult to arrest and which when not removed looked as if it were absorbed and again and again re secreted. The retention of the hyperacid residuum gave rise further to catarrh and to atonic dilatation In some severe cases relief was ultimately obtained by vomiting and this was associated sometimes with reflux of bile from the duodenum The treatment to be selected depended upon the severity of the condition and the history of the case and he would only refer to general principles In mild degrees associated with constipation the correction of this might be sufficient. In these an alkali taken some time before food neutralised any acid residuum and facilitated the transformation of the starchy elements of the next meal In other instances relief was obtained by the administration of even a small dose of an alkali or as soon as discomfort began Dr Russell had had no success with the administration of acids in this condition, though in some other gastric disorders they were beneficial The diet had also to be determined by the severity of the symptoms. In some cases the prohibition of the commoner forms of starch, such as potato and untoasted bread, was sufficient, in others still greater care had to be exercised in the selection of the most readily digested carbohydrate. Another class might get over their immediate discomfort by the use for a day or two of readily digested pure proteid diet and the gradual addition to this of the most soluble carbohydrates available. In the severest cases he found the removal of the gastric residuum the speediest means of temporary cure He held that the condition being a chemical dyscrasia and not a neurosis a permanent cure or anything approaching it could only be looked for from a dietary adapted to counteract or to prevent the chemical dyscrasia. Considerations determining the dietary were: (1) the proteids ought to be reduced to a physiological minimum and ought to be so selected and cooked as to be easy and ready of digestion, (2) the starches should be as much altered as possible, and (3) the quantity of food should not exceed the physiological requirements Proceeding on these broad lines patients might be confidently assured of recovery and continuance in abstinence and simple living would carry with it the reward of physical and mental well being —Dr GIBSON, Dr J O AFFLECK, Dr JAMES RITCHIE, Dr G LOVELL GULLAND, Dr UNDERHILL, Dr GEORGE HUNTER, Dr BOYD, and Mr STILES took part in the discussion which followed and Dr RUSSELL replied.

Mr R B PURVES read a paper on Disinfection of the Hands. He first considered the question of protecting the hands, especially at non operating times, from all forms of infection He insisted on the importance of such "abstinence" and pointed out that, short of the ideal means of wearing gloves constantly except while operating the infective potentiality of the hands could be materially diminished (1) by the use of gloves when out of doors, (2) by always washing the hands after examining cases, (3) by keeping the nails short, and (4) by wearing rubber gloves when operating on infective conditions, dressing septic wounds, and handling pathological specimens, also by using finger stalls for rectal, vaginal, and oral examinations He advocated a nightly toilet of the hands—viz., washing, thoroughly drying, and applying an emollient. He referred to Krönig and Reinike's observation that hands, if not re infected, become in time germ free, and described his own investigations on the hands of washerwomen. He made 60 observations at different times of the day and found that after five hours' washing cultures yielded no cocci He emphasised the importance of a prolonged preliminary cleansing and suggested a regular system for adoption in the use of the nail brush He urged the necessity of keeping the nails as short as possible and considered that at least ten minutes should be devoted to preliminary cleansing He considered a sand glass—a time recorder—an advantage. He then referred to subsequent purification and believed that success depended rather on the thoroughness with which a method was carried out than upon the use of any particular one and that it was only in most favourable circumstances that active disinfectants could be safely dispensed with. He then touched on Ahlfeld's and Mikulicz's methods. In order to avoid the cost of the alcohol a trial for a year had been given in the Deaconess Hospital to Mikulicz's spirit soap prepared with methylated spirit. Although results improved slightly the soap had to be abandoned on account of its irritating properties He entered into the question of gloves and advocated their more general use, particularly of thread gloves, in the ligating and suturing stage to prevent "implantation infection." He deprecated the use of a reel of catgut unless gloves were worn to prevent contact with the fingers He pointed out the value of control cultures from the hands and operation area and showed a chart with a tabulated series of observations illustrating the facts that the right hand was less frequently sterile than the left and that the patient's skin was sterile in only about one half of cases —Mr STILES, Dr W ALLAN JAMIESON, Mr LUNDIE, Mr C W CATHCART, Mr ALEXIS THOMSON, and Dr J HAIG FERGUSSON discussed the paper and Mr PURVES replied

EDINBURGH OBSTETRICAL SOCIETY

Exhibition of Specimens —Abdominal Section.—Tubal Gestation.

A MEETING of this society was held on March 11th, Dr JAMES RITCHIE, the President, being in the chair

Dr ANGUS MACDONALD showed (1) An Enlarged Thyroid from a Newly born Infant, causing fatal tracheal compression, and (2) two Enlarged Tubes removed for Hydrosalpinx.

Dr JESSIE MACGREGOR showed an Œdematous Fœtus, the thyroid, liver, and other organs under the microscope exhibited excessive small cell infiltration

Other specimens were shown by Dr F W N HAULTAIN, Dr W FORDYCE, Dr J W BALLANTYNE, and Dr J H FERGUSON

Dr ALBERT E MORISON (West Hartlepool) read notes on five cases of Abdominal Section for emergencies during pregnancy When the first patient was in labour her pelvis was found to be so much diminished in the transverse diameter as only to admit about two fingers, but the sacro subpubic diameter was apparently normal It was impossible to deliver a child *per vias naturales*, so a Porro-Tait operation was performed The operation occupied less than 25 minutes and the patient did not lose more than half an ounce of blood The child was alive and well and the mother made a good recovery In the second case a Porro-Tait operation was performed for sarcoma of the uterus in the ninth month of the patient's third pregnancy The condition of the uterus rendered normal labour improbable. The patient recovered from the operation but died 117 days later, the child was alive and well. In the third case a Porro Tait operation was performed for contracted pelvis. This patient was 4 feet 6½ inches in height, with a history of rickets The operation lasted 35 minutes, the child was alive and the mother's recovery was uneventful In the fourth case Cæsarean section was performed for eclampsia at the sixth month of pregnancy The patient, who was a primipara, had felt in very good health till five months previously, when she fell heavily on the ice, striking her abdomen. After that she suffered from constant headache The urine was found to show one-half albumin Fits occurred and after chloral, bromide of potassium, and injection of saline solution in the median basilic vein had been tried without benefit Cæsarean section was performed. The fœtus had been dead for some time The patient's recovery was uninterrupted except for a slight fit one week after the operation. The urine at the time contained no albumin. In the fifth case rupture of the uterus occurred in the fourth month of the patient's tenth pregnancy The uterus was removed supravaginally The patient rallied and after a severe attack of pneumonia and a prolonged convalescence she ultimately recovered.

Professor J A C KYNOCH (Dundee) communicated a paper entitled "Three Cases of Unruptured Tubal Gestation with Notes of Cases simulating this Condition" In the first case a fixed tender swelling about as thick as the forefinger was felt posteriorly to, and to the right of, the uterus After four weeks, during which pain and hæmorrhagic discharge continued, cœliotomy was performed. The appendages on the right side were found to be adherent and the tube distended, the tube contained a sac with blood stained fluid and numerous branching villi were seen. This patient had been in a hospital 18 months before with all the signs of ectopic gestation on the opposite side, terminating in the formation of a hæmatoma in the broad ligament which became absorbed in six weeks In the second case milk was present in the right breast and a distended tube was found lying to the right and behind the uterus. Cœliotomy was performed and the appendages on the right side were removed The tube was enlarged at the isthmus, a probe could be passed through the fimbriated extremity There was no blood in the pouch of Douglas The tube contained laminated blood clot round a cavity with a smooth membrane containing red tinged fluid but no trace of an embryo. In the third case the patient had menstruated regularly, but there was continuous hæmorrhagic discharge from the last period till admission to hospital. She had only suffered from pain in the right side for four days She was examined under chloroform, when it was found that the uterus was enlarged and that there was a distended tube behind it. On palpating the swelling Professor Kynoch felt something suddenly give way and on recovery from the anæsthetic the patient looked collapsed, pale, restless and showed all the signs of internal hæmorrhage. Cœliotomy was performed when a large amount of clot was found in the abdomen. The right tube was drawn up, when a rent admitting the point of the little finger was found on the posterior wall of the swelling with a blood clot protruding The appendage was removed, the tube was swollen to the size of a pigeon s egg and filled with blood clot, no embryo was found As to the treatment of such cases Professor Kynoch said that most authorities would agree with Werth in regarding an unruptured tube containing a living embryo as demanding immediate removal and permitting no conservative treatment, but with the death of the embryo debateable ground was approached. The researches of Kühne and others went to demonstrate that after the death of the embryo the cells of Langerhans' layer were capable of growing, penetrating, and causing rupture of the tubal wall. In such a condition the necessity for operative interference would arise. In conclusion Professor Kynoch discovered the diagnosis of ectopic gestation from (1) simple abortion occurring in normal pregnancy, (2) hæmorrhage into the ovary, Graafian follicle, or ovarian cyst, and (3) tubal condition with cystic ovarian disease associated with menstrual disturbance —Remarks were made by Dr HAULTAIN, Dr MORISON, Dr BALLANTYNE, Dr. FORDYCE, and Dr J LAMOND LACKIE.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY —A clinical meeting of this society was held on March 6th, Mr. Rickard W Lloyd, the President being in the chair —Mr. J R. Lunn showed a case of Dislocation of the Left Patella in a woman, aged 38 years. Ten days before admission to the St. Marylebone Infirmary she had fallen and had injured her knee. The diagnosis of dislocation of the patella outwards was confirmed by the x rays An attempt to reduce the dislocation under chloroform failed. The patient now found difficulty in getting up from a chair and in extending the knee, but once up she could walk fairly well.—Mr J Jackson Clarke considered that the internal lateral ligament had been ruptured and should be sutured —Mr C R B Keetley said that dislocation of the patella if left unreduced might cause permanent disability although in some unreduced cases strength and good movement might return. In this case he advised operation.—Mr J E. S Fraser thought that the external lateral attachment should be divided and the internal sutured Then careful movements with fixation should be used. This treatment failing it might be necessary to resect.—Mr Jackson Clarke showed two cases of Spinal Caries in children In one patient the products of disintegration were able to escape by means of a psoas abscess. In the other child there was pressure on the cord resulting in paraplegia. To relieve this costo-transversectomy had been performed with good result.—Mr Keetley remarked that time cured nearly every case of paraplegia due to caries if the patient lived long enough He had trephined through the transverse process some time before Vincent of Lyons had suggested a similar procedure. The patient recovered but not probably as the result of the operation. Doubtless the operation had its uses, but the main thing was fixation of the spine, which was best done by means of a plaster jacket.—Mr L. A. Bidwell showed two cases The first was a patient who up to last September had suffered from indigestion for two or three years and vomiting for six months. His stomach was dilated below his umbilicus He was much emaciated The case was regarded as one of cicatricial stenosis of the pylorus and gastro-enterostomy was advised On Sept. 5th the abdomen was opened and a new growth was found at the pylorus. It was not adherent and no enlarged glands were found in the hilum of the liver The jejunum was attached to the posterior surface of the stomach by Halsted's method. A month later pylorectomy was suggested to the patient and this was done on Oct. 4th. The patient left the hospital one month after operation and returned to work and had increased two stones in weight. The second case was that of a patient, aged 60 years, who had had a large tumour in connexion with the left shoulder for nearly 50 years Photographs of the growth were taken in St. Mary's Hospital in 1857 From these it appeared that at that time the general condition suggested sarcoma Excision of the head of the humerus was advised but was refused The tumour was now of the size of a cocoa nut It gave no trouble except for the mechanical interference with movement. There was no sign of pressure or of wasting of the limb There were enlarged veins over the tumour and the skin was rather adherent The diagnosis seemed to lie between simple exostosis and ossifying sarcoma. Probably it was a case of the latter in which ossification had proceeded to such an extent as to destroy completely the sarcomatous elements.—Mr Paton agreed with the diagnosis of ossified sarcoma.—Mr Arthur Evans had under his care a man with an equally large bony tumour of the upper end of the femur A portion removed proved to be osteo-sarcoma. The patient was then treated by injection of Coley's fluid. The tumour was now smaller and harder than it was —Mr J G Pardoe showed a man, aged 37 years, who for three years had suffered with painful and frequent micturition pyuria, and occasional hæmaturia. 18 months ago he had had a stone removed by litholapaxy In a few months the symptoms returned In November last year another stone was detected, crushed, and removed by Mr Pardoe. On the following day the urine was free from blood and clearer 48 hours after the operation there were pain in the left side of the lower abdomen and tenderness above Poupart's ligament. Three days after the operation the tenderness had extended to the umbilicus, the abdomen was motionless, and the pulse was 130, although the temperature was only 99 5° F The abdomen was opened to the left of the middle line and an offensive accumulation of slough, urine, and pus was found. Drainage tubes were inserted. The peritoneum apparently was not opened. Recovery was tedious but uneventful Probably there had been some pouch or sacculus in the bladder to account for the formation of stones and this weak portion of the bladder was damaged in the litholapaxy, with consequent abscess —Dr E. A. Saunders showed a woman, aged 55 years, suffering from myxœdema. Two years ago she began to suffer from frequent headaches, giddiness, and sensation of swelling and choking in the throat. For the last two winters her fingers had gone white in the cold weather. During the last year she had grown stouter than she was formerly and her features had swollen. As regards the possible causation of the disease it was interesting to note that she had a caseating glandular abscess in the neck incised in 1902. The fact that the thyroid gland in these cases was found to be small and fibrotic suggested an analogy with Addison s disease. Possibly the fibrotic process in the thyroid might be the expression of a chronic tuberculous inflammation leading to atrophy of the glandular elements —Dr A. Whitfield showed a child, aged four years, who had been treated by the x rays for Microsporon (Ringworm of the Scalp) After 13 or 14 exposures the hairs on the patches had completely fallen out. In two or three months healthy hair grew again. Dr Whitfield thought that the x rays offered a clean and certain method of cure in circumscribed cases but should only be used with great care. For the disseminated stumps such as were seen in old cases, he thought croton oil needling would still hold its place

MANCHESTER MEDICAL SOCIETY —A meeting of this society was held on March 4th Dr A. M Edge, the President, being in the chair —Dr A. Knyvett Gordon read a paper on Some Points in the Treatment of Laryngeal Diphtheria He pointed out that whereas in America and on the continent of Europe the laryngeal obstruction of diphtheria was treated almost exclusively by intubation of the larynx, in this country tracheotomy was still largely preferred. But tracheotomy as it was described in the later text-books of surgery consisted in the performance of a dissecting operation, under chloroform, through a long incision. To this a diathetic error than a neurosis was further supported by the experience that the mechanical removal of the hyperacid residuum in severe cases more promptly overcame the attack than any dietetic or medicinal measure, as if the withdrawal of the acid removed an overflow which otherwise was difficult to arrest and which when not removed looked as if it were absorbed and again and again re secreted. The retention of the hyperacid residuum gave rise further to catarrh and to atonic dilatation In some severe cases relief was ultimately obtained by vomiting and this was associated sometimes with reflux of bile from the duodenum The treatment to be selected depended upon the severity of the condition and the history of the case and he would only refer to general principles. In mild degrees associated with constipation the correction of this might be sufficient. In these an alkali taken some time before food neutralised any acid residuum and facilitated the transformation of the starchy elements of the next meal In other instances relief was obtained by the administration of even a small dose of an alkali or as soon as discomfort began Dr Russell had had no success with the administration of acids in this condition, though in some other gastric disorders they were beneficial The diet had also to be determined by the severity of the symptoms In some cases the prohibition of the commoner forms of starch, such as potato and untoasted bread, was sufficient, in others still greater care had to be exercised in the selection of the most readily digested carbohydrate. Another class might get over their immediate discomfort by the use for a day or two of readily digested pure proteid diet and the gradual addition to this of the most soluble carbohydrates available. In the severest cases he found the removal of the gastric residuum the speediest means of temporary cure He held that the condition being a chemical dyscrasia and not a neurosis a permanent cure or anything approaching it could only be looked for from a dietary adapted to counteract or to prevent the chemical dyscrasia. Considerations determining the dietary were: (1) the proteids ought to be reduced to a physiological minimum and ought to be so selected and cooked as to be easy and ready of digestion, (2) the starches should be as much altered as possible, and (3) the quantity of food should not exceed the physiological requirements Proceeding on these broad lines patients might be confidently assured of recovery and continuance in abstinence and simple living would carry with it the reward of physical and mental well being —Dr Gibson, Dr J O Affleck, Dr James Ritchie, Dr G Lovell Gulland, Dr Underhill, Dr George Hunter, Dr Boyd, and Mr Stiles took part in the discussion which followed and Dr Russell replied.

Mr R B Purves read a paper on Disinfection of the Hands He first considered the question of protecting the hands, especially at non operating times, from all forms of infection He insisted on the importance of such "abstinence" and pointed out that, short of the ideal means of wearing gloves constantly except while operating the infective potentiality of the hands could be materially diminished (1) by the use of gloves when out of doors, (2) by always washing the hands after examining cases, (3) by keeping the nails short, and (4) by wearing rubber gloves when operating on infective conditions, dressing septic wounds, and handling pathological specimens, also by using finger stalls for rectal, vaginal, and oral examinations He advocated a nightly toilet of the hands—viz., washing, thoroughly drying, and applying an emollient He referred to Krönig and Reinike's observation that hands, if not re-infected, become in time germ free, and described his own investigations on the hands of washerwomen. He made 60 observations at different times of the day and found that after five hours' washing cultures yielded no cocci He emphasised the importance of a prolonged preliminary cleansing and suggested a regular system for adoption in the use of the nail brush He urged the necessity of keeping the nails as short as possible and considered that at least ten minutes should be devoted to preliminary cleansing He considered a sand glass—a time recorder—an advantage He then referred to subsequent purification and believed that success depended rather on the thoroughness with which a method was carried out than upon the use of any particular one and that it was only in most favourable circumstances that active disinfectants could be safely dispensed with. He then touched on Ahlfeld's and Mikulicz's methods. In order to avoid the cost of the alcohol a trial for a year had been given in the Deaconess Hospital to Mikulicz's spirit soap prepared with methylated spirit. Although results improved slightly the soap had to be abandoned on account of its irritating properties He entered into the question of gloves and advocated their more general use, particularly of thread gloves, in the ligating and suturing stage to prevent "implantation infection." He deprecated the use of a reel of catgut unless gloves were worn to prevent contact with the fingers. He pointed out the value of control cultures from the hands and operation area and showed a chart with a tabulated series of observations illustrating the facts that the right hand was less frequently sterile than the left and that the patient's skin was sterile in only about one half of cases —Mr Stiles, Dr W Allan Jamieson, Mr Lundie, Mr C W Cathcart, Mr Alexis Thomson, and Dr J Haig Fergusson discussed the paper and Mr Purves replied.

EDINBURGH OBSTETRICAL SOCIETY

Exhibition of Specimens —Abdominal Section.—Tubal Gestation.

A meeting of this society was held on March 11th, Dr James Ritchie, the President, being in the chair

Dr Angus Macdonald showed (1) An Enlarged Thyroid from a Newly born Infant, causing fatal tracheal compression, and (2) two Enlarged Tubes removed for Hydrosalpinx

Dr Jessie Macgregor showed an Œdematous Fœtus, the thyroid, liver, and other organs under the microscope exhibited excessive small cell infiltration

Other specimens were shown by Dr F W N Haultain, Dr W Fordyce, Dr J W Ballantyne, and Dr J H. Ferguson

Dr Albert E Morison (West Hartlepool) read notes on five cases of Abdominal Section for emergencies during pregnancy When the first patient was in labour her pelvis was found to be so much diminished in the transverse diameter as only to admit about two fingers, but the sacro subpubic diameter was apparently normal It was impossible to deliver a child *per vias naturales*, so a Porro-Tait operation was performed The operation occupied less than 25 minutes and the patient did not lose more than half an ounce of blood The child was alive and well and the mother made a good recovery In the second case a Porro Tait operation was performed for sarcoma of the uterus in the ninth month of the patient's third pregnancy The condition of the uterus rendered normal labour improbable. The patient recovered from the operation but died 117 days later, the child was alive and well. In the third case a Porro Tait operation was performed for contracted pelvis. This patient was 4 feet 6½ inches in height, with a history of rickets The operation lasted 35 minutes, the child was alive and the mother's recovery was uneventful In the fourth case Cæsarean section was performed for eclampsia at the sixth month of pregnancy The patient, who was a primipara, had felt in very good health till five months previously, when she fell heavily on the ice, striking her abdomen After that she suffered from constant headache The urine was found to show one-half albumin Fits occurred and after chloral, bromide of potassium, and injection of saline solution in the median basilic vein had been tried without benefit Cæsarean section was performed. The fœtus had been dead for some time The patient's recovery was uninterrupted except for a slight fit one week after the operation The urine at the time contained no albumin In the fifth case rupture of the uterus occurred in the fourth month of the patient's tenth pregnancy The uterus was removed supravaginally The patient rallied and after a severe attack of pneumonia and a prolonged convalescence she ultimately recovered.

Professor J A C Kynoch (Dundee) communicated a paper entitled "Three Cases of Unruptured Tubal Gestation with Notes of Cases simulating this Condition" In the first case a fixed tender swelling about as thick as the forefinger was felt posteriorly to, and to the right of, the uterus After four weeks, during which pain and hæmorrhagic discharge continued, cœliotomy was performed. The appendages on the right side were found to be adherent and the tube distended, the tube contained a sac with blood stained fluid and numerous branching villi were seen. This patient had been in a hospital 18 months before with all the signs of ectopic gestation on the opposite side, terminating in the formation of a hæmatoma in the broad ligament which been struck by the extreme variability of the interval between the occasion of injury and the subsequent parotitis, by the absence of general septicaemia or pyaemia, and by the mortality of the disease in very many cases, so that dryness of the mouth could not be invoked as a factor. The theory of infection from the mouth, though to some extent supported by the only post-mortem examination he had made, in no way accounted for parotitis occurring more frequently after pelvic than other operations. A nervous influence of the pelvic organs upon the parotid gland seemed to be the most reasonable cause.—Dr. W. Duncan said that the few cases which he had had of parotitis following abdominal section he had always attributed to sepsis; in future he would always investigate the condition of the mouth.—Dr. Bedford Fenwick, Dr. F. A. Purcell, Dr. C. H. Bennett, Dr. J. J. Macan, and Dr. Hugh Woods also spoke.—Dr. Macnaughton-Jones, in reply, said that death in cervical phlegmon might be from direct pressure, but implication of the inhibitory nerve supply would account for cardiac failure. Parotitis was but one of the complications he had ascribed to infection from the mouth and he had expressly stated that it might have a neural origin.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The monthly meeting of this society was held on March 11th, Surgeon-Major Mark Robinson, I.M.S. (retired), the President, being in the chair.—Mr. A. Marmaduke Sheild gave an address on Some Recent Experiences in Diseases of the Breast. The commoner diseases of the breast were reviewed and many practical hints in connexion with their diagnosis and treatment were given. As regarded mammary abscess it was important to adopt prophylactic measures during pregnancy and the nursing period. During the latter period the mouth of the infant should be regularly washed out with glycerine and borax or 1 in 4000 perchloride of mercury and glycerine. Mammary abscess was invariably due to pyogenic organisms entering the gland through the nipple. It was important to diagnose between pus and engorgement of the milk ducts. An incision should never be made unless it was certain that pus was present. If an operation was necessary an anæsthetic should always be given. A free incision should be made and any burrowing passages should be opened up and a counter opening was often desirable. Chronic mammary abscess was often tuberculous and simulated cancer. It should be always incised before removal of the breast was resorted to. Cysts were usually milk cysts (galactocele) or serous cysts, the latter were single or multiple. If there were two or three tumours in a breast it was not cancer. Cysts were painful, early cancer was not painful. Cysts varied in tension, sometimes being hard on one day and fluctuating on another. If it were certain that a cyst was a simple serous one it could be tapped and injected with carbolic acid and glycerine (30 or 40 drops) or it could be dissected out. If there were growths in the cyst or if the breast was riddled with cysts the whole of the organ should be removed. After referring to the characteristic signs of cancer Mr Sheild mentioned a useful diagnostic test—placing the palmar surface of the hand over the surface of the breast and greatly pressing backwards. The tumour if due to a mastitis disappeared—if it did not there was something more than mastitis. Retraction of the nipple occurred in abscess of the breast while soft cancer might not pucker the breast or the nipples. Enlarged glands were never absent though often they were not to be felt. Cases not suitable for operation included those in which the skin was extensively involved, cases of cancer in young pregnant women, and cases of atrophic cancer. Mr Sheild showed a number of excellent drawings.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on March 11th, Dr J J Pringle being in the chair.—Dr F G Penrose showed a child aged one year and seven months, suffering from a Bullous Eruption which had been first noticed one week after birth. The eruption affected the limbs only and showed some tendency to occur in groups. The diagnosis offered was that of pemphigus circinatus.—Mr Willmott H. Evans showed a characteristic example of Pityriasis Rubra Pilaris in a woman aged 56 years. The disease was of seven months' duration and affected chiefly the neck, arms and legs. On the lower extremities the rash was diffuse and scaly, but on the neck and upper extremities it consisted of miliary follicular papules each with a central horny plug.—Dr J J Pringle showed a woman who had noticed a Lump beneath the Skin on the right side of the neck [illegible] weeks before. Shortly after this other lumps appeared, and at the time of exhibition she was covered all over with numerous subcutaneous nodules. Quite recently, also, she had developed severe headache and ptosis of the left eye. One of the lumps removed had been excised and showed the case to be one of multiple sarcoma, the primary growth not having been detected.—Dr. J. H. Sequeira showed a woman suffering from Alopecia Areata associated with Anæmia Nervosa.—Dr. J. M. H. MacLeod showed a boy who had suffered from Hyperidrosis since he was six months old. This especially affected the face and hands. On the nose, occupying the whole of the lower two-thirds, the skin was red and covered with minute papules upon which small drops of sweat were constantly standing. The disease was a good example of that described by Jadassohn as granulosis rubra nasi.—Dr. A. Whitfield showed a child, aged six years, who exhibited an extraordinary eruption of unknown nature. On the centres of both cheeks and the chin were patches of [illegible] inflammatory eruption with some infiltration and atrophy. The lobes of the ears were occupied by bright purple cushion-like swellings with hard [illegible]. On both elbows and wrists were raised, [illegible] which showed a faint yellow colour on pressure. Some ill-defined patches also existed on the legs. The buttocks showed an eruption like that on the cheeks. The case had existed for about three years and the child had enjoyed perfect health. No diagnosis was offered and no member of the society had seen a similar case before.—Dr. F. Parkes Weber showed a man with a Solitary Growth on the Right Side of the Scrotum of two years' duration. The question arose as to whether it was malignant [illegible] or a granuloma.—Dr. T. Colcott Fox showed a case of Large Papular Syphilide almost all the papules being as large as a shilling. The infiltration was marked but quite superficial and the disease was of quite recent origin.—Mr. Arthur Shillitoe showed a case of Grouped Large Papular Syphilide scattered all over the back and limbs in a patient who had contracted syphilis nine months previously and had undergone no treatment for it.—Dr James Galloway showed a case of Urticaria Pigmentosa.—Dr E Stainer showed a case of Mycosis Fungoides.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on March 4th, the President, Dr H W Langley Browne being in the chair.—Dr C E Purslow showed the placenta and membranes from a case of complete Placenta Prævia. They formed a complete sac, the only aperture in which was the hole in the centre of the placenta through which the fœtus had been delivered.—Dr Purslow also showed Uterine Appendages with an Accessory Ovary. They had been removed from a single woman, 29 years old, for severe menorrhagia which had persisted for two years in spite of every method of treatment. The ovaries presented several small cysts and on the left side there was a well marked accessory ovary of the size of a pea situated in the upper edge of the broad ligament about three-quarters of an inch from the ovary proper and immediately beneath the fimbriated extremity of the tube.—Mr Christopher Martin showed a specimen consisting of the Appendages of the Uterus and the whole of the Vagina removed for extreme prolapse. The patient was a widow past the menopause and no form of pessary could be retained. The operation was severe and was only performed as a last resource. The patient made a slow but complete recovery.—Mr William Billington showed specimens from a case of Neuro-fibromatosis (von Recklinghausen's disease). The patient was a man, 33 years of age, who died shortly after the removal of a large swelling on his lingual nerve which almost filled up his mouth and seriously interfered with breathing and swallowing. At the age of three the patient fell and cut his right cheek. Two years later a lump appeared. This gradually increased in size, and in spite of two successful operations the right cheek remained very much larger than the left. Other lumps appeared in other parts of the body, some of which were subcutaneous. The patient remained in good health and suffered very little inconvenience until the year before his death. The specimens which were shown consisted of the lumbar plexus and its branches with the upper part of the sacral plexus. The nerve showed marked diffused thickening at intervals, giving rise to a fusiform swelling. A tumour was found in the lower half of the spinal cord rather larger than an almond. This gave rise to no symptoms [illegible] life and operation intubation of the larynx was certainly preferable and it was with this that it was usually compared The points in favour of the rapid method through a short incision, the knife being guided entirely by the touch of the left forefinger which was kept on the lower edge of the cricoid cartilage until the tracheal dilators were inserted, were (1) that it could be performed almost as quickly as intubation, (2) that no anæsthetic was required, (3) that the trachea was more likely to be opened in the middle line, (4) that the tracheal fascia was disturbed as little as possible, and (5) that it was an easier operation. Compared with intubation it had the advantages (1) that the relief of the obstruction was more complete, (2) that the rest of the child was less disturbed, (3) that subsequent feeding was easier, especially in the hands of an imperfectly trained nurse, (4) that it was more easy to remove false membrane, especially when this was below the tracheal wound and in large masses, and (5) that complete rest was afforded to the larynx. Stress was also laid on the fact that it was possible to remove the tube as soon as an intubation cannula in the same circumstances, tracheotomy tubes being usually left in too long Among the indications for operation the amount of obstruction was not so important as the effect that it was having on the patient, in this connexion restlessness and the amount of epigastric recession were often misleading, the presence of cyanosis being the more important indication for operation. The after treatment was most important and consisted chiefly in insuring absolute rest to the patient, it was particularly important to avoid the use of feathers, steam tents and over feeding, in the majority of cases starvation for 24 hours was desirable. In these circumstances Dr Gordon believed that tracheotomy was usually preferable to intubation, but there were a few cases in which intubation might be resorted to when it was important not to leave even as mall scar The reason why intubation gave such good results in America and on the continent was that antitoxin was given as a rule earlier in the course of the disease than in this country —Dr T A. Goodfellow read a paper on a case of Pylephlebitis following Perityphlitis, in which the occurrence of a period of delirium early in the course of the disease, followed by a series of severe and frequently repeated rigors lasting throughout the whole illness left the diagnosis for a long time in doubt No definite abdominal tumour was felt, but laparotomy discovered the presence of a chronically inflamed appendix with a broken down lymphatic gland containing old pus. Their removal failed to relieve the symptoms, although at a second operation the only abnormal condition found was the presence of ascites Subsequently pus was found in the liver (that organ having become enlarged in the later stages of the disease) but its evacuation was not followed by any improvement and the patient died. The pus from the liver gave cultivations of the bacillus coli and the streptococcus citreus The case extended over 59 days, during the last 46 of which urobilinuria with a moderate amount of jaundice was present A short summary of the present state of knowledge regarding urobilinuria was given.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM —A meeting of this society was held on March 2nd, Dr Urban Pritchard being in the chair —The discussion on papers relating to Tuberculosis of the Ear, Nose, and Naso-pharynx, already mentioned in THE LANCET of Feb 21st, p 522, was resumed —The President remarked that the theory put forward by Dr W Jobson Horne did not quite account for the chief cause of the pain—namely, pressure on nerve endings, in tuberculous cases there was not very acute inflammation, not very great pressure and therefore absence of acute pain. In selecting cases for operation he thought that the important point was not the amount of local damage, but the general condition of the patient.—Mr C A Ballance thought that tuberculosis of the temporal bone region should be treated and thought of both pathologically and surgically, exactly as tuberculosis of any other bone was. He agreed that where the disease was extensive the operation should be done by stages. He believed that in a considerable number of cases the temporal bone was the seat of the primary disease, and he felt sure that it was the primary source of the disease which it was the surgeon's duty to attack at the earliest possible moment and that it should be removed completely without regard to the facial nerve.—Mr A E Cumberbatch considered that it should not be a question of operating upon these cases simply because they were tuberculous. The question was whether it was possible to remove the disease. If so, it should be done.—Dr A. L. Whitehead referred to a series of records of fatal cases of ear disease. Of the last 100 cases there were only 12 which were distinctly tuberculous, and of these all but three were under two years of age Of the three over that age all had advanced tuberculous mischief elsewhere, chiefly in the lungs. —Mr Hugh E Jones said that it was worthy of consideration whether bovine tuberculosis might not be responsible for the primary mastoid affections.—Mr A. H Cheatle remarked that many times in young children with profuse discharge from the ear, which was suspected to be tuberculous, the smell had been characteristic.—Mr Richard Lake described two cases in which, although there was well marked tuberculous disease of the tympanum and aural accessory centres, yet the pus which flowed down the Eustachian tube had not infected the larynx He thought that cases of tubercle of the middle ear coming on during pulmonary tuberculosis were far commoner in this country than on the continent. He would not advise grafting after operating upon a mastoid for tuberculous disease because of the risk of shutting in tuberculous granulations.—Dr J Dundas Grant quoted a case showing how insidious may be the origin of tuberculous disease of the middle ear even in a robust-looking individual.—Dr. V H. Wyatt Wingrave, Dr Jobson Horne, and Dr W A. Milligan then replied to the various speakers who had taken part in the discussion. Dr Milligan said that the discussion had shown that primary tuberculous disease of the ear was more common than had been supposed and hence the primary focus of the disease should be removed and the whole question of operation should be determined by the general condition of the patient. He advised grafting in tuberculous cases because the disease did not often invade the bone deeply, and it was quite possible to eradicate it in the majority of cases. In his experience the stapes was seldom thrown off as a sequestrum in non tuberculous cases, the reverse being the case in tuberculous disease.—Dr C H Fagge showed two specimens of Tuberculous Disease of the Middle Ear —Mr Cheatle showed a case of Healed Tuberculosis of the Middle Ear and seven specimens of Tuberculosis of the Temporal Bone in Infants, four of whom died from tuberculous meningitis.—Dr James Kerr Love exhibited skiagrams of the Temporal Bone having special reference to the auditory apparatus and the surgical anatomy of the mastoid antrum.

BRITISH GYNÆCOLOGICAL SOCIETY —A meeting of this society was held on March 12th Dr Heywood Smith, the President, being in the chair —Dr H Macnaughton Jones read a paper on the importance of attention to the Mouth in Operations on the Pelvic Viscera, with notes of a fatal case of Parotitis. He reviewed the bacteriology of the mouth in health and during various diseased states He noticed especially the products formed during the presence of pyorrhœa alveolaris with carious teeth and illustrated the effects caused by such morbid conditions of the mouth by cases which had come under his notice in which gastric complications associated with foul conditions of the mouth, and great fœtor, parotitis, with angina Ludovici (post-operative) occurred. He reviewed the arguments for the neural and septic origin of the parotitis, asserting that there were ample grounds for believing in both causes In such patients he thought that the prolonged administration of ether was more likely to increase and to prolong such gastric and digestive troubles than chloroform Doubtless parotitis was often a coincidence rather than a sequence of an operation. He detailed the particulars of a case of parotitis which commenced on the fourteenth day after an operation for cystocele with uterine prolapse and hæmorrhoids The case terminated fatally, notwithstanding free and deep incisions, on the fifteenth day of the attack. Here unquestionably the mischief began in the teeth and mouth. The patient had suffered for some time from the former and had been under dental care immediately before the operation As a factor in causing post-operative digestive disturbances, or such graver complications as that mentioned, or sepsis, the condition of the teeth and buccal cavity before and subsequently to an operation was important The best disinfectants were formalin, peroxide of hydrogen, sulphurous acid, and boric acid, with a basis of glyco-thymoline. Benzo-naphthol had in his experience a most salutary effect in such cases —The President asked what had been the immediate cause of death in fatal cases of parotitis.—Mr Stephen Paget (a visitor) said that in the 101 cases which he had collected he had been struck by the extreme variability of the interval between the operation or injury and the subsequent parotitis, by the absence of general septicæmia or pyæmia, and by the triviality of the trauma in very many cases, so that dryness of the mouth could not be invoked as a factor. The theory of infection from the mouth, though to some extent supported by the only post-mortem examination he had made, in no way accounted for parotitis occurring more frequently after pelvic than other operations A nervous influence of the pelvic organs upon the parotid gland seemed to be the most reasonable cause.—Dr W Duncan said that the few cases which he had had of parotitis following abdominal section he had always attributed to sepsis, in future he would always investigate the condition of the mouth —Dr Bedford Fenwick, Dr F A. Purcell, Dr C H. Bennett, Dr J J Macan, and Dr Hugh Woods also spoke.—Dr Macnaughton Jones, in reply, said that death in cervical phlegmon might be from direct pressure, but implication of the inhibitory nerve supply would account for cardiac failure Parotitis was but one of the complications he had attributed to infection from the mouth and he had expressly stated that it might have a neural origin

SOUTH-WEST LONDON MEDICAL SOCIETY —The monthly meeting of this society was held on March 11th, Surgeon Major Mark Robinson, I M S (retired), the President, being in the chair —Mr A. Marmaduke Sheild gave an address on Some Recent Experiences in Diseases of the Breast The commoner diseases of the breast were reviewed and many practical hints in connexion with their diagnosis and treatment were given. As regarded mammary abscess it was important to adopt prophylactic measures during pregnancy and the nursing period. During the latter period the mouth of the infant should be regularly washed out with glycerine and borax or 1 in 4000 perchloride of mercury and glycerine. Mammary abscess was invariably due to pyogenic organisms entering the gland through the nipples It was important to diagnose between pus and engorgement of the milk ducts An incision should never be made unless it was certain that pus was present. If an operation was necessary an anæsthetic should always be given. A free incision should be made and any burrowing passages should be opened up and a counter opening was often desirable. Chronic mammary abscess was often tuberculous and simulated cancer It should be always incised before removal of the breast was resorted to Cysts were usually milk cysts (galactocele) or serous cysts, the latter were single or multiple If there were two or three tumours in a breast it was not cancer Cysts were painful, early cancer was not painful. Cysts varied in tension, sometimes being hard on one day and fluctuating on another If it were certain that a cyst was a simple serous one it could be tapped and injected with carbolic acid and glycerine (30 or 40 drops) or it could be dissected out If there were growths in the cyst or if the breast was riddled with cysts the whole of the organ should be removed. After referring to the characteristic signs of cancer Mr Sheild mentioned a useful diagnostic test—placing the palmar surface of the hand over the surface of the breast and greatly pressing backwards The tumour if due to a mastitis disappeared—if it did not there was something more than mastitis Retraction of the nipple occurred in abscess of the breast, while soft cancer might not pucker the breast or the nipples Enlarged glands were never absent though often they were not to be felt Cases not suitable for operation included those in which the skin was extensively involved, cases of cancer in young pregnant women, and cases of atrophic cancer Mr Sheild showed a number of excellent drawings.

DERMATOLOGICAL SOCIETY OF LONDON —A meeting of this society was held on March 11th, Dr J J Pringle being in the chair —Dr F G Penrose showed a child, aged one year and seven months suffering from a Bullous Eruption which had been first noticed one week after birth The eruption affected the limbs only and showed some tendency to occur in groups The diagnosis offered was that of pemphigus circinatus —Mr Willmott H. Evans showed a characteristic example of Pityriasis-Rubra Pilaris in a woman, aged 56 years The disease was of seven months duration and affected chiefly the neck arms and legs On the lower extremities the rash was diffuse and scaly, but on the neck and upper extremities it consisted of miliary follicular papules each with a central horny plug —Dr J J Pringle showed a woman who had noticed a Lump beneath the Skin on the right side of the trunk seven weeks before. Shortly after this other lumps appeared, and at the time of exhibition she was covered all over with numerous subcutaneous nodules Quite recently, also, she had developed severe headache and ptosis of the left eye One of the little tumours had been excised and showed the case to be one of multiple sarcoma, the primary growth not having been detected.—Dr J H Sequeira showed a woman suffering from Alopecia Areata associated with Anorexia Nervosa.—Dr J M H MacLeod showed a boy who had suffered from Hyperidrosis since he was six months old This especially affected the nose and hands. On the nose, occupying the whole of the lower two thirds, the skin was red and covered with minute papules upon which small drops of sweat were constantly standing The disease was a good example of that described by Jadassohn as granulosis rubra nasi —Dr A. Whitfield showed a child, aged six years, who exhibited an extraordinary eruption of unknown nature On the centres of both cheeks and the chin were patches of persistent erythematous eruption with some infiltration and atrophy The lobes of the ears were occupied by bright purple cushion like swellings with hard cartilaginous edges On both elbows and wrists were raised, reddish, infiltrated discs which showed a faint yellowish colour on pressure Some ill defined patches also existed on the legs The buttocks showed an eruption like that on the cheeks The disease had existed for about three years and the child had enjoyed perfect health. No diagnosis was offered and no member of the society had seen a similar case before —Dr F Parkes Weber showed a man with a Softish Growth on the Right Side of the Scrotum of two years duration The question arose as to whether it was malignant disease or a granuloma —Dr T Colcott Fox showed a case of Large Papular Syphilide, almost all the papules being as large as a shilling. The infiltration was marked but quite superficial and the disease was of quite recent origin —Mr Arthur Shillitoe showed a case of Grouped Large Papular Syphilide scattered all over the back and limbs in a patient who had contracted syphilis nine months previously and had undergone no treatment for it.—Dr James Galloway showed a case of Urticaria Pigmentosa.—Dr E Stainer showed a case of Mycosis Fungoides.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on March 4th, the President Dr H. W Langley Browne, being in the chair —Dr C E. Purslow showed the placenta and membranes from a case of complete Placenta Prævia —They formed a complete sac the only aperture in which was the hole in the centre of the placenta through which the fœtus had been delivered.—Dr Purslow also showed Uterine Appendages with an Accessory Ovary They had been removed from a single woman, 29 years old, for severe menorrhagia which had persisted for two years in spite of every method of treatment. The ovaries presented several small cysts and on the left side there was a well marked accessory ovary of the size of a pea situated in the upper edge of the broad ligament about three-quarters of an inch from the ovary proper and immediately beneath the fimbriated extremity of the tube.—Mr Christopher Martin showed a specimen consisting of the Appendages of the Uterus and the whole of the Vagina removed for extreme prolapse. The patient was a widow past the menopause and no form of pessary could be retained. The operation was severe and was only performed as a last resource. Reviews and Notices of Books.

Experimentelle Untersuchungen über die entzündliche Neubildung von Bindegewebe (*Experimental Investigations on the Inflammatory Growth of Connective Tissue*) Von Dr Med ALEXANDER MAXIMOW, St Petersburg Jena Gustav Fischer. 1902. Pp 262 and 13 plates Price 20 marks.

UNDER the above title Dr Alexander Maximow has published a very lengthy monograph in book form describing in detail the results of a long series of experiments undertaken by him to discover the exact manner in which connective tissue is formed and regenerated. This very important piece of research has been carried out in Professor E. Ziegler's pathological laboratory in Freiburg, a laboratory from which at one time and another a great deal of work on this subject has emanated The controversial and vexed question of connective tissue formation has a literature of its own which is little less than prodigious and within recent years there is hardly a pathologist of repute who has not contributed some item more or less important towards the elucidation of the vital processes concerned in what is generally called inflammatory growth Indeed, Professor Ziegler himself largely owes his great reputation as a pathologist to his classical "glass chamber" investigations on this very subject, and it has been Dr Maximow's task to substantiate the greater part of his investigations as it has been to reconcile many of the conflicting theories which have been adduced on the general processes of inflammation. Inflammatory new growth has been explained as due to the coalescence and growth of leucocytes derived from the blood stream, to the growth of migratory cells belonging to the lymphatic system, or to specially modified cells of the connective tissue and to the outgrowth of processes of pre-existing connective tissue cells According to Dr Maximow it is to the fibroblasts which are the ordinarily connective tissue cells that we must look for the formation of permanent new tissue. Certain other cells also take part in the preliminary stages of this growth Their function, however is only temporary and evanescent, they act, as it were, as pioneers or carriers to the fibroblasts, which are the permanent bricklayers and masons. These pioneer cells belong chiefly to two classes—firstly, ordinary leucocytes which are of the multinuclear granular variety and which migrate from the blood vessels to the seat of inflammation, and secondly, certain uninuclear round cells, sometimes called lymphocytes and in the author's nomenclature described as polyblasts. These latter cells or polyblasts occasionally originate from pre-existing migratory cells of the connective tissue type. They also appear to develop from clasmatocytes and from the adventitious cells of the blood vessels. However the vast majority of polyblasts are *ordinary* lymphocytes which have migrated from the blood stream. Whether, however they make their appearance at the seat of inflammation directly from the blood stream or wander thither from the intercellular spaces of the connective tissue, it is suggested that these polyblasts are probably of one nature only although under varying conditions of environment their morphological character may have been distinctly differentiated. The ordinary leucocytes and polyblasts, although paving the way for the permanent work of the fibroblasts, are incapable of independent formation of enduring tissue. Leucocytes for the most part degenerate and disintegrate, possibly providing food material for the workers of the permanent structure. The histological methods whereby the author has been enabled to carry out his inquiries are very thorough, complete, and ingenious, and the microscopic appearances of the preparations are very beautifully illustrated at the end of the work in a series of plates.

This monograph is not only a very valuable contribution to the histology of connective tissue formation and regeneration, but it throws very important light on the general processes of inflammation and although possibly it does not represent the last words which have to be said on these biological processes nevertheless it must be regarded as the most trustworthy account which has yet been published.

Die Antikörper Resultate früherer Forschungen und Neue Versuche (*The Anti bodies Results of Previous Researches and New Experiments*) By Dr EMIL FREIHERR of Dungern. With two Drawings and Four Curves. Jena Gustav Fischer 1902. Pp. 114 Price 2s 6d

THE first part of this treatise gives a concise and interesting survey of the researches which have led to the development of the present theory of immunity After a full consideration of the antitoxins and of Ehrlich's theories in regard to receptors, amboceptors, and complements the author proceeds to deal with the other anti bodies, the agglutinins, lysins, cytotoxins, and precipitins, and discusses their origin, nature, formation, and action so far as they have been elucidated by present research In the second part Dr Freiherr describes his own researches. These were instituted to inquire further into the nature and formation of the anti bodies and for this purpose he chose the precipitins. In his experiments he employed the blood plasma of molluscs and injected it into rabbits. An account of these experiments is not called for here but some of the conclusions which he draws from his researches may be mentioned. He finds that precipitins are of an albuminous nature and are specific for the particular sera by which they are called into being, that the precipitable substance of an injected foreign serum enters into some combination with the cells of the organism before katabolic destruction, that such a combination of an injected foreign serum with the cells of the organism is hindered and delayed by a previous injection of another different serum, and that consequently while different sera when injected call forth specific precipitins the same cells of the organism are employed in the reaction On the other hand, it is shown that a previous injection of one serum predisposes the organism to take up the precipitable substance from a second injection of the same serum rather than that of a different serum. The formation of precipitin takes a definite time to develop after injection and its course may be represented by a curve. Finally, Dr Freiherr describes an interesting experiment in which he was able to demonstrate a local formation of precipitin by injection of the serum into the anterior chamber of a rabbit's eye.

Hygiene und Diätetik der Stoffwechselkrankheiten. (*Hygiene and Dietetics of the Diseases of Metabolism*) By F SCHILLING Leipsic H. Hartung and Son 1903. Pp 345 Price 5.50 marks

THE number of diseases which are recognised as due to faulty metabolism is now so considerable that it is as remarkable that Dr. Schilling has been able to condense an intelligible account of the chief varieties within the limits of 345 pages as that a volume so replete with scientific detail has not assumed even larger dimensions It is however, logically certain that if the diseases now acknowledged *to* belong to this classification are indeed due to perverted metabolism the list must be greatly extended in the near future. For inasmuch as all physiological processes represent the activities of protoplasm—in other words, "metabolism"—and inasmuch as pathological processes are was the only lesion present in the central portion of the nervous system.—Mr George Heaton read a paper on the Palliative and Operative Treatment of Enlarged Prostate and showed one of his cases

Laryngological Society of London —A meeting of this society was held on March 6th, Dr P McBride, the President, being in the chair —Dr A. Bronner showed a microscopic specimen of Columnar celled Carcinoma of the Naso-pharynx from a patient who had been under observation for four and a half years —Sir Felix Semon remarked that it was a well-known experience that malignant disease in the nose and naso-pharynx usually pursued a slow course. —Dr W H Kelson showed (1) a man with Dislocation of Bones of the Nose due to Polypi, and (2) Bleeding Polypus in a girl, with microscopic section —Dr H. Tilley showed a case illustrating the Result of Operative Treatment of Adhesion of the Soft Palate to the Posterior Pharyngeal Wall in Tertiary Syphilis —Mr F J Steward showed a case of Clonic Contraction of the palate, adductors of the vocal cords, and certain other muscles The patient had a staggering and reeling gait and slightly increased knee and plantar reflexes, but no other signs indicative of lesion of the nervous system.—Sir Felix Semon considered that the gait was not typically tabetic and suggested the probability of cerebellar tumour —Mr E. Cresswell Baber showed (1) a Tumour of the Vestibule from a woman, aged 26 years, with microscopic section, and (2) a Tongue Depressor for exposing the tonsil. —Mr E D Vinrace showed a case of Lupus (?) of the Nose and Face in a woman about 60 years of age. The case was discussed by Dr H W Fitzgerald Powell, Dr W Hill, Dr J Dundas Grant, and Mr F H. Westmacott.—The President showed a case of Anosmia in a man aged 39 years, who had lost the sense of smell in the beginning of 1901. The principal feature of interest in the case was the intermittent character of the anosmia. The case was discussed by Mr Baber, Mr F de Havilland Hall, Dr Grant, Dr J Donelan, Dr L H Pegler, and Dr P Watson Williams —Dr H L Lack showed various Microscopic Specimens and a man (shown at the January meeting) who was suffering from Spastic Aphonia affecting the speaking but not the singing voice, and who had now completely recovered his power of speech.—Dr Donelan showed a case of Perforation of the Nasal Septum (? trauma or syphilis)

Nottingham Medico-Chirurgical Society —A meeting of this society was held on March 4th, Dr C H. Cattle being in the chair —Mr R. G Hogarth showed the following cases 1 A boy on whom Œsophagotomy had been performed for removal of a toothed clock wheel one inch in diameter from the thoracic portion of the œsophagus where it had been lodged for six days, the œsophagus was opened just above the left sterno clavicular joint. 2. A boy after an extensive operation for Excision of Tuberculous Glands in the Right Side of the Neck, the glands were very numerous but only one or two had broken down centrally 3. Two boys after Excision of the Hip joint. 4 A child after Erasion of the Knee-joint for Tuberculous Disease 5 A case of Congenital Dislocation of the Hip (with skiagram) in which the Lorenz operation had been tried unsuccessfully 6 A boy after Tarsectomy for Talipes Equino-varus —The cases were discussed by Dr Cattle, Dr J S Bolton and Mr W M Willis.—Mr Hogarth read a paper on the Diagnosis of Affections of the Hip-joint. He urged that examination *per rectum* of the condition of the pelvic bones should be more frequently used and advocated early operation in those cases in which tuberculous disease occurred in the acetabulum or in the neck of the femur

Torquay Medical Society —A meeting of this society was held on Feb 19th, Dr F D Crowdy, the President, being in the chair —Dr T Horton related the case of a young man upon whom he had successfully operated by the suprapubic route for the removal of the broken end of a gum elastic catheter from the bladder The case was somewhat mysterious as there was no apparent reason why he should have used a catheter The patient had also the scar of a previous similar operation and another scar in the loin where his kidney had been cut down upon —Mr H. T Newling read a paper on Accidental Hæmorrhage in which after reviewing various former methods of treating this condition and their unsatisfactory results, he commended the method advocated by Dr R. P Ranken Lyle, but first brought under notice by Dr W J Smyly, late master of the Rotunda Hospital, Dublin, which consisted in tightly plugging the vagina with sterilised cotton wool tampons after the bladder and rectum had been emptied, the object being to compress the uterine arteries against the pelvic walls, and then applying an abdominal binder and a perineal band. Mr Newling read notes of two cases in which this treatment was adopted with perfect success —A discussion followed

Edinburgh Royal Medical Society —A meeting of this society was held on March 13th, Dr A B Ross being in the chair —Dr W H Prentice read a paper on Some Aspects of Gynæcology, laying stress on the importance of gynæcological training to the general practitioner on account of diagnosis and treatment. The paper was illustrated by reference to cases which had come under the notice of Dr Prentice and which had been wrongly diagnosed by general practitioners. He gave a *résumé* of the treatment of cases most likely to be met with in general practice and this he considered chiefly from the point of view of treatment medically —Dr A H Firth read notes on two medical cases The first was the case of a miner with symptoms of Cerebral Tumour At the post-mortem examination a gliosarcoma affecting the frontal lobes was found. Dr Firth exhibited sections of the brain and also a microscopic section through the frontal regions The second was a case of Extensive Cancer of the Liver in a middle aged woman. The post-mortem examination showed that the liver was greatly enlarged, weighing 14 pounds. It was the seat of primary carcinoma. Sections of the liver were exhibited.

Glasgow Pathological and Clinical Society —A meeting of this society was held on March 9th, Dr A. E Maylard, the President, being in the chair —Dr A Maitland Ramsay showed a case of Detachment of the Retina which had been treated by subconjunctival injection of saline solution, the fields of vision of eight other cases treated in the same way were also shown, in six there was marked improvement but in the two other cases there was none He also showed a case of Ophthalmoplegia and one of Tuberculous Iritis.—Dr J Crawford Renton read notes of (1) the case of a girl, aged 12 years, operated on for a Ruptured Appendix and ten days afterwards for obstruction of the bowel, and (2) a case in which Recurrent Attacks of Obstruction of the Bowel were caused by a gall stone impacted in a contracting ulcer of the ascending colon.—Dr J Wyllie Nicol showed a patient who was the subject of Generalised Favus.—The President showed specimens of Bowel from two successful cases of Enterectomy —Dr J M Cowan and Dr A. R. Ferguson showed several specimens illustrating Congenital Cardiac Anomalies.

Folkestone Medical Society —A meeting of this society was held on March 6th, Dr T Eastes, the President, being in the chair —Mr M. G Yunge-Bateman read a paper on the Influence of Isolation of Infectious Diseases as applied to Folkestone Charts were exhibited representing figures covering a period of ten years, divided into two equal parts—the first that of inefficient isolation and the second that of efficient isolation due to the more perfect control of infectious cases and to better accommodation and administration He showed that the percentage of isolated cases to the notified cases had increased 20 per cent and that the case mortality had been reduced about 50 per cent —The President expressed the opinion that it was hopeless to endeavour to isolate a patient in a private house for any length of time —Dr P G Lewis, Mr W F Chambers, Dr A E Larking Mr W P Barrett, Mr J W T Gilbert, and Dr W L Chubb took part in the discussion

Glasgow Northern Medical Society —A meeting of this society was held on March 3rd, the President, Dr J Steel Muir, being in the chair —A discussion was opened upon the following subject, "Can anything special be done by the medical practitioner to diminish the frequency of, and to lessen the mortality from, cancer of the uterus?" Dr J K. Kelly opened the discussion by reading a paper dealing with the question and Dr John Ritchie, Mr C F Spinks, Dr James Todd, the President, and Mr J Rutherford spoke, while Dr Kelly replied.

Medical Magistrate —Mr Edward England Phillips, M.R.C S Eng, L.R.C P Edin, has been placed on the commission of the peace for the city of Bath. Mr Phillips was mayor of Bath in 1902 and is already a justice of the peace for Essex and Somersetshire, having been added to the commission in 1886 hich sooner or later he is brought into contact in medical actice. Thus a reference to Raoult's law we should have ought would have afforded the opportunity of mentioning yoscopy as applied to the examination of urine Again, we ight anticipate a reference to the currents employed in ectro-therapeutics and once more in the section on light urely there was the opportunity of discussing treatment by ctinic rays in however small a paragraph The book is ased on the author's lectures for the intermediate examina ons in science at the University of London and for that amination we are quite sure that it will be helpful, but we il to see in what way it is adapted for the specific needs f the medical student.

Organic Chemistry By W H. PERKIN, jun., Ph.D, F.R.S., and F STANLEY KIPPING, Ph D, D Sc., F R.S New and revised edition London and Edinburgh W and R. Chambers, Limited. 1902. Pp 635 Price 7*s* 6*d* —When this book was issued in parts some years ago we ventured to hope that the authors might see their way to incorporate the sections into one volume, so favourably were we impressed with the lucid way in which the facts were presented Not only has this been done, but recently a chapter dealing with the more important constituents of plants and animals has been added in the form of an appendix with a separate index. We have already expressed the opinion that the book admirably meets the requirements of the medical student and since this important chapter has been added our opinion in this regard has been considerably strengthened. With many students organic chemistry is undoubtedly a difficult subject and it is not easy to limit the extent of their studies exactly to their particular requirements The tendency of many teachers is to force the student to face a great number of facts which the exploration of the organic field is constantly bringing to light. The present volume keeps within certain bounds, giving a course of organic chemistry sufficient for the medical student's purpose There is time enough to study complex organic problems when he has mastered the primary points and classification and he will find that the foundations of the science are here dealt with in a clear, comprehensive way without sacrificing details which may be of medical import.

Points of Practical Interest in Gynæcology By H MACNAUGHTON JONES, M D, M Ch Q U I. With 24 plates Third edition. London Bailliere, Tindall and Cox. 1902. Pp. 183 Price 4*s* 6*d* net —The fact that second and third editions of this book have been called for within the year shows that it has met with a ready appreciation. The author has certainly, in the words of Dr Johnson whom he quotes in the preface to the first edition, "stored his mind with acquired knowledge,' and that he is successful in recalling this knowledge in an acceptable manner for the benefit of others is shown by the success of this little work. The most interesting section is that dealing with affections of the female genitalia as causal factors of the neuroses of insanity and their special bearing on the operative treatment of the insane. In other chapters are discussed conservatism in gynæcology and its influence on operative technique, the indications for the operation of hysterectomy, and retroversion of the uterus

The Pharmacological Action and Therapeutical Uses of the Nitrites and Allied Compounds By the late DANIEL JOHN LEECH M D, D Sc., F R.C P Lond Edited by R B WILDE, M D Lond., M Sc. Vict, M.R.C P Lond Manchester Sherratt and Hughes 1902 Pp. 187 Price 10*s* 6*d* —The masterly disquisition on the pharmacological action and therapeutic uses of the nitrites and allied compounds which formed the subject of the Croonian Lectures in 1893 by the late Professor Leech is the principal feature of this book, the publication of which the profession will keenly appreciate since it is the most valuable contribution on the action of that interesting class of compounds containing the NO_2 group The Croonian Lectures were delivered in 1893, but the present volume represents the views held by Professor Leech in 1900 The first chapter contains the exceedingly interesting and classical discourse on "The Relation of Pharmacology to Therapeutics' which formed the introductory lecture delivered at the Owens College on May 1st, 1884 This is followed by a chapter on spiritus ætheris nitrosi and then one on nitrite of ethyl and other nitrites At the end of the book is a somewhat lengthy list of references to the bibliography on the subject which is followed by 28 plates showing muscle curves and contractions and sphygmographic tracings The late Professor Leech's thoroughness of method was well known and to him we owe a contribution of the utmost pharmacological importance, shedding a strong light on the relation between the constitution of nitro-compounds and their therapeutic action.

A Junior Chemistry By E A. TYLOR, B A. London Methuen and Co 1902 Pp 228 Price 2*s* 6*d* —Though we deplore the plethora of elementary manuals of chemistry we can find no objection to this little volume, for it sets forth in a plain and intelligent way the rudiments of chemical science. On the whole we like the author's plan which is to insert experimental directions in the subject matter dealing with theoretical considerations We should have thought that some small reference to helion would have been made considering its significance in regard to the chemistry of the sun and the earth. The author's method of instruction is obviously correct, for he has omitted summaries because ' they help the lazy boy to avoid thinking for himself." "Thinking for himself" is the secret of attaining sound knowledge

The Modern Treatment of Sewage By H C H SHENTON London S Edgecumbe Rogers 1902. Pp 117 Price 2*s* 6*d* —This is a reprint of a number of useful little notes on the engineering side of sewage problems which appeared in the *Local Government Journal* It is evidently the work of a practical man and the chapters are written clearly and will be read with advantage by those desirous of a practical acquaintance with the subject. The account of the methods of disposal is decidedly good and instructive.

Medical Guide to the Hot Mineral Baths at Bath. Published by the Baths Committee of the Bath Corporation Pp 111 —This is an official guide issued by the Bath Corporation and contains useful information for the practitioner bearing upon the methods of treatment at this celebrated health resort. Probably the equipment at Bath comprises all known methods employed in balneo-therapeutic practice The book contains a number of extracts from the report of the Special Commission of THE LANCET (*vide* THE LANCET, Oct. 14th, 1899, p 1055), which "supplied a wealth of valuable information of an unimpeachable character which is here unsparingly drawn upon."

A Manual for Assistants' Examination, Apothecaries Hall By MABEL F STANLEY, Qualified Dispenser, Apothecaries' Hall London Henry Renshaw 1902. Pp 281.—The fact that this book is intended for examination purposes is not disguised and no doubt it will form a useful notebook for those studying for the assistants' examination. We can take no exception to the facts presented under chemistry and materia medica, but of course, both subjects are treated in a scrappy way When the author expresses the view that this little manual should prove a useful adjunct to the ordinary text-books' on materia medica, chemistry and pharmacy criticism is disarmed We hope that the reader will bear in mind the word adjunct."

Sewage Works Analyses By GILBERT J FOWLER M.Sc. Vict, F I.C London P S. King and Son Pp 135. Price 6*s* —In view of the great strides that are now being made in regard to the purification of sewage by bacterial agencies it is important that a systematic scheme for the but narrowly removed from those which are physiological, it follows that all morbid conditions, whether giving rise to structural or to functional change, must in a sense be regarded as of metabolic origin. Thus, strictly speaking, such widely separated pathological conditions as hysteria and tumour formation have the same right to be regarded as diseases of metabolism as have diabetes and gout. The author, however, wisely limits his survey of the diseases belonging to this category to those concerning the nature of which there can be no possible doubt—namely, to that closely allied trio, gout, diabetes, and obesity (*Fettsucht*) and to the auto-intoxications, scurvy, Basedow's disease, myxœdema, and rickets.

The simplest introduction to the study of disturbed metabolism is to survey the same processes in what may be termed normal or physiological conditions, and conformably with this view the opening chapters of the volume are devoted to the elucidation of the chemical and physical processes of protoplasm which result in digestion, assimilation, and dissimilation. Readers are next informed as to the cause and effects of pathological disturbance of these normal processes and the treatment by hygienic and dietetic measures is fully discussed. Finally, the various groups of symptoms described as independent diseases are explained at length and the appropriate treatment is suggested. The manner in which the author handles his subject is altogether admirable and if the reader is disappointed at finding that the biological secret of gout, diabetes, and all the other diseases due to faults of metabolism is still to be discovered his mind at least will be disabused of many of the fallacious beliefs which have heretofore stood in the way of a rational understanding of the vital processes of health and disease. While we have nothing but approval for the want of prejudice and for the extremely impartial manner in which Dr. Schilling handles so controversial a subject as that of tissue metabolism, we cannot help thinking that he has hardly credited the nervous system with the respect to which it is entitled, both as an instrument for the maintenance of normal metabolism and as a factor in the production of those disturbances of equilibrium which give rise to symptoms of disease. While admitting that the nervous system is itself dependent for its activity on the chemical changes which occur in its molecular constitution, it cannot be doubted that it exercises the most potent influence, not only on special metabolism but also on what may be called the vegetative metabolism of all tissues throughout the body.

Although it is hardly probable that this excellent little work will be translated into the English language, nevertheless the original German is written in such an easy and simple manner that anyone who has a slight acquaintance with the German language will find no difficulty in understanding the greater part of the contents and all those who are interested in the subject of metabolism are strongly advised to read it.

Anæsthetics: a Practical Handbook. By J. BLUMFELD, M.D. Cantab. London: Baillière, Tindall, and Cox. 1902. Pp. 109. Illustrated. Price 2s. 6d. net.

WE gather from Dr. Blumfeld's preface that the object he has placed before him in writing this handbook is to supply students with such general information about anæsthetics as may suffice for the needs of examinations and ordinary practice. Within the limits that he thus prescribes for himself the author has been quite successful. No doubt the exigencies of space have obliged him to confine his attention to three anæsthetics—nitrous oxide, chloroform, and ether—but students might have been told that other useful anæsthetics are available and, further, that local anæsthesia offers a wide field of utility if employed with knowledge and judgment. At times we are referred to the writings of other anæsthetists for descriptions of apparatus which had they been included in his volume would have increased its utility. The average student, however, does not refer to larger books and such information as an author does not think it necessary to give the student is content to do without.

Nitrous oxide is dealt with after a brief account of the action of anæsthetics. The use of this gas alone, with air or oxygen, is clearly given. The mixture of nitrous oxide and oxygen is rightly described as an unsatisfactory combination for prolonged operations. It is common to prolong anæsthesia in dental practice by the use of a nasal tube or nose cap and Dr. Blumfeld has taken pains to describe the methods and has done so well, and only very careful writing can do more than indicate the methods of using these valuable contrivances. As no mention is made of Coxon's mouth injector tube for "continuous gas" we suppose its use does not appeal to Dr. Blumfeld. The mode of employment of ether alone or in sequence to nitrous oxide is carefully given and many valuable suggestions are made in this connexion. Clover's method of giving gas with ether by his larger apparatus does not find a place in this manual, but Ormsby's inhaler and the use of Rendle's mask are described. The reference on p. 44 to Mr. W. Tyrrell's two bottle method is somewhat misleading. It is there stated that "ether is sometimes given from the bottle of a Junker's inhaler when chloroform is being also used." The whole object of the method as we understand it is to give chloroform and if occasion arise, to be able to blend some ether vapour with it. The ether is an adjunct and not the predominant partner.

An excellent chapter on chloroform follows, a chapter which appears to us to be of especial value. The illustration of Junker's apparatus might have been replaced by one of the more modern and improved patterns which offer safeguards to many of the undoubted dangers incidental to Dr. Junker's original apparatus. The description given, however, makes up for the error in illustration, as the original apparatus is not dealt with, but the more modern type is taken, in which twin tubes are used and the method of using the inhaler is very well and clearly set forth. Succeeding chapters introduce the subjects Anæsthetics in Succession and in Mixtures, Choice of Anæsthetic, Dangers and Troubles incidental to Anæsthesia, and Position of the Patient and his Preparation and the After-effects. Dr. Blumfeld has compressed into these few chapters much that is valuable and his directions are sensible, succinctly put, and accurate. We can recommend the book as an excellent primer for the use of beginners, while we are sure that more advanced students may benefit by reading with care the closing chapters. Dr. Blumfeld has set himself to accomplish a certain task and we consider that he has performed that task well and in a useful manner. His descriptions are excellent and he possesses a clear style.

LIBRARY TABLE

A Text-book of Physics. By R. A. LEHFELDT, D.Sc. London: Edward Arnold. 1902. Pp. 304. Price 6s.—According to the author in his preface this book has been written from the point of view of the student of medicine in the hope of attracting attention to the intimate dependence of physiology on physical principles and at the same time of supplying a practical handbook of moderate dimensions containing so much of physics as the student amongst his many other claims can find time for. We are aware of the tendency to overburden the medical student with the facts of the collateral sciences, but surely we might expect that a text-book of physics written from the point of view of the student of medicine would have afforded an opportunity of dealing with those physical phenomena with

THE LANCET.

LONDON SATURDAY, MARCH 21, 1903

Efficient Nursing in Workhouses

In most of the workhouses of England and Wales the question of the hour is—What is the best means of insuring a continuous supply of competent nurses for the sick and infirm people forming a large proportion of the inmates of those institutions? The question is one that has steadily gained in urgency during the past 30 years—that is, since the commencement of the movement for the improvement of the treatment of the sick and disabled in workhouses. This movement resulted, after the passing of Mr GATHORNE HARDY'S Act, in the provision of properly constituted wards under the management of skilled and responsible salaried officials The abolition of the pauper nurse was thus assured But notwithstanding the fact that the numbers of trained nurses have been increasing year by year the demand for them is still unsatisfied. In the country workhouses, especially in the smaller institutions, the supply has been quite inadequate, so that the Local Government Board recently nominated a departmental committee and allotted to it the task of finding the cause of and suggesting the remedy for, the difficulty in obtaining probationers. The report issued by that committee has already received critical attention in our columns[1] It was recently dealt with at length by the Hon. SYDNEY HOLLAND in his presidential address to the members of the Central Poor law Conference at their thirty first meeting Many years and much energy have been devoted by Mr HOLLAND to the study of nursing questions, his position as Poor law guardian and as chairman of three London hospitals has afforded him a practical acquaintance with their varied aspects and his observations are consequently worthy of careful attention. We therefore propose to consider some of the points brought forward in his address, which we have before us, and to do so in connexion with the report of the departmental committee on the subject

Mention may first be made of the explanation advanced by Mr HOLLAND, and indorsed by other experts on nursing questions, as to the causes of the difficulty in obtaining and keeping a skilled nursing staff in a small workhouse The most potent of the causes is stated to be "putting a trained woman under an untrained matron" and by so doing making the position of the former person intolerable. While the argument is sound there is something to be said against this wording of the case No evidence has been given that the "intolerable" position is due to the fact of the matron being untrained. No assurance can be furnished that it would be changed into a tolerable position if the matron were trained. On the contrary, many nursing authorities competent to advise on such a matter have condemned the proposal to appoint persons to the double office of workhouse matron and superintendent nurse. The reason for this condemnation will be readily understood after an examination of the General Consolidated Order of the Poor-law Board of 1847 relating to the work of the matron In any but the minor workhouses matrons could not possibly perform in an efficient manner all the duties detailed in that Order and at the same time act as superintendent nurses. There are also medical grounds for pronouncing such a combination of offices to be very undesirable In seeking the causes of the disinclination of nurses to remain in workhouses it will be of some assistance to remember the conditions enumerated below which may, and generally do, affect the comfort of the nurse to a greater or less extent. The powers of the master and matron are almost unlimited in small matters There is no trivial incident in the daily routine that they may not take cognisance of and invest with a gravity out of all proportion to its nature. They have a right to interfere in all questions of discipline, and "discipline" may be a very elastic term, embracing many things in the management of sick wards. The matron is in most workhouses the wife of the master A nurse rarely offends the former without offending the latter The nurse, then, has powerful odds against her on any point of difference, for in dealing with officials the master and matron generally agree. Although the General Order of the Local Government Board of 1897 debars the matron from interfering with the actual medical treatment of the sick it leaves her, under the older order, with many responsibilities for the food, the clothing the discipline, and the condition of the patients and sick wards. She has, therefore, ample opportunity for making her presence felt in the infirmary wards. In other words, there are in the department for the sick all the disadvantages of dual control The hours of duty for the nurse are often very long The times and duration of recreation periods are meagre and badly defined They are not infrequently moved or shortened without notice on the ground of urgency Then there is the difficulty of spending the hours of recreation in an enjoyable or satisfying manner, for many country workhouses are removed from facilities for amusement or instruction. Quite apart from the conditions above stated there are others which make nursing in a small workhouse unattractive to young women. Two may be mentioned. The first is the small number of cases of acute disease to be studied, together with the absence of any instructive amount of surgery Candidates are soon able to realise that with the limited teaching possible they cannot hope to compete with their more highly-educated sisters from the large towns The second is the small market value of the three years' training certificate compared with that of one obtained at a general hospital or a large infirmary

Turning now to the report of the departmental committee we find indications of the methods by the adoption of which it is hoped to bring about a more satisfactory state of affairs in the nursing at country workhouses. Among several suggestions, all more or less good but somewhat lacking in thoroughness, two immediately attract attention chiefly by their unexpectedness and by the fact that they are in opposition to the views and tenets which have steadily taken possession of the minds of all teachers of nursing during the past 20 years. One is that there shall be a examination of sewage and sewage effluents should be adopted by which the character of both may be determined. This little book, therefore, comes at an opportune time and moreover it is written by one whose experience of sewage processes cannot be doubted. Mr. Fowler is the superintendent and chemist of the Manchester corporation sewage works and the methods of analysis described are those which are adopted there. Little more need be said. The methods have been approved by experience and supply all that is required to form an opinion as to the character of the sewage presented for treatment and as to the extent of purification effected by a given process. The book is one to be consulted by all those having anything to do with the control of methods of purification. We cannot help thinking that 6*s.* is rather a high price for this small volume.

---

[1] THE LANCET, Feb. 14th, 1903, p. 451.

The Guide to South Africa, 1902–1903 Edition. Edited annually by G. SAMLER BROWN and G. GORDON BROWN for the Union Castle Mail Steamship Company, Limited. London: Sampson Low, Marston, and Co., Limited. Cape Town: J. C. Juta and Co. Pp. 274 and maps. Price 2*s.* 6*d.*—This guide is said to be for the use of tourists, sportsmen, invalids, and settlers. It gives information on how to get to South Africa, with various details as to living in the country, together with articles on farming, mining, health and health resorts, manufactures, and sport. In the article on sport we are glad to see a protest against the hideous and wanton destruction which has caused the entire disappearance of some species of animals and rendered others extremely rare. On p. 260 there is surely a slip. The writer says, "Three species of ibis are found including the red sacred ibis (*Ibis Aethiopica*)." Now the sacred ibis is not red but white with a black head and black tail coverts, while the red ibis (*Eudocimus ruber*) is, we believe, only found in South America and occasionally in the Southern States, unless, indeed, the writer means by "red" the glossy ibis (*Plegadis falcinellus*) which at some seasons of the year is of a ruddy chestnut colour, but in any case the sacred ibis is not red. The information given in the book is very full and should be of use to the various classes of readers for whom it is intended.

Briefhand or Orthographic Shorthand. Published by the author, F. W. WHITE, 26, Browning road, Manor park, E. Price 6*d.*—Various attempts have been made to construct a system of shorthand capable of being written more rapidly than our cumbrous cursive script but which shall be at the same time almost as legible, though, judging from manuscripts which reach us, legibility is not always a characteristic of longhand writing. "Briefhand" is yet another attempt in this direction and is intended, according to the author's preface, "chiefly for the use of the general public who have not the time, the inclination, nor the necessity to study a complicated system of shorthand." It is impossible to judge of the utility of any system of shorthand until it has been used in actual practice, but from a glance through the pages of this little pamphlet, we are inclined to think that "Briefhand" may prove useful for the class of persons indicated by the author. The alphabet, which can be memorised in ten minutes or less (the characters being formed from the diacritical portions of the Roman capital letters), has been ingeniously constructed, while the rules for writing are extremely simple. Provision is made for sounds peculiar to the French, German, and Spanish languages. The inventor believes that the system may also prove useful to writers of phonetic shorthand as an aid in securing the correct spelling of peculiar and unfamiliar words and names which may be difficult to represent by a system of shorthand in which words are written as sounded and not as spelt. In a covering letter the author assures us that he himself, a writer of phonography, does not find that the two systems clash in actual practice.

MEDICINE AND THE LAW

Madame Spitzner's Great Museum.

THE case of Désiree Spitzner and Léon Dekaesmaeker came before the Recorder at the March sessions of the Central Criminal Court. These persons, foreigners, were charged with exhibiting waxwork figures alleged to be obscene and with publishing a catalogue of the exhibition. A description of the figures appeared in THE LANCET of Jan. 24th, p. 275. At the Old Bailey counsel for the prosecution representing the National Vigilance Association applied that the case should stand over until the next sessions upon terms that meanwhile the whole of the exhibits should be removed abroad and that there should be no opposition to an order being made at the Marlborough street police-court for the destruction of the catalogues in the hands of the police. This application the Recorder granted, the persons charged being admitted to bail. Mr. Kennedy, the magistrate who was subsequently asked to make the order for destroying the catalogues, seems to have expressed regret at the leniency of the course adopted. Many, however, will consider that it was on the whole satisfactory, for it causes the withdrawal of the exhibition from England without entailing the discussion which usually follows trials of this kind upon the relative indecency of various works, scientific, literary, and artistic, and upon the views held upon such subjects in various countries. The law in England in such matters was laid down by Chief Justice Cockburn in 1868 in the case of the pamphlet entitled "The Confessional Unmasked." He had referred during the course of the argument to the position occupied by medical works. In the course of his judgment he said: "The test of obscenity is this, whether the tendency of the matter charged as obscenity is to deprave and corrupt those whose minds are open to such immoral influences, and into whose hands a publication of this kind may fall." It is not difficult to apply the principle here laid down to the case of Spitzner and Dekaesmaeker.

A Test of Sobriety.

At the Southwark police-court medical evidence was called recently on behalf of a defendant, a publican, who was charged with being intoxicated upon his own premises. The evidence of the medical man was that the defendant could stand with his eyes shut without swaying, could turn quickly, walk perfectly straight, read and write, and that he could also repeat distinctly, "the scene is truly rural." Mr. Paul Taylor seems to have been struck with the severity of this last test, remarking that it was not a fair one as many men were unable to say "truly rural" even when unquestionably sober. Presumably what the learned magistrate meant was that failure to articulate the prescribed words would not have been convincing evidence of insobriety. In the case in question as the defendant had responded satisfactorily the medical man had applied a test which was decidedly effective. The magistrate in the end dismissed the charge against the accused.

Insanitary Houses.

At the Southwark police court on March 14th James Mahoney, of Friern road, East Dulwich, was fined £10 and 4*s.* costs for failing to remedy the insanitary condition of two houses of which he was the owner. He had apparently had his attention called to their condition and had failed to comply with an order for their improvement. Evidence was given that in one of them inhabited by eight persons there was no water supply for flushing purposes. The magistrate was further informed that the defendant owned property all over the metropolis, that whenever he was fined he went to prison instead of paying the money, and that a distress would not obtain it as the goods in the house where the defendant lived were owned by his wife. In these circumstances Mr. Paul Taylor fixed a month as the term of imprisonment to be undergone in default of the fine being paid, at which defendant loudly protested. Cases of this kind show that however much passive resistance and delay may be capable of effecting the law can apply considerable pressure in sanitary matters if those who have the power to set the law in motion will do so with energy and perseverance.

Among structures which act as "thoracic supports" of the diaphragm are enumerated "all the structures within the thorax, the heart, the great vessels, the pericardium, the cervical and mediastinal fasciæ, the dorsal mesentery of the thorax and the lungs," the latter by virtue of the negative pressure within the pleural sacs.

Attention is drawn by Dr. Keith to a striking difference in the level of the diaphragm during rest (expiration) in different adult bodies, a difference so great that what corresponds to full inspiration in one individual may be the level of full expiration in another. The evidence, however, that the individuals with low diaphragms suffered from what would be clinically described as enteroptosis needs some corroboration. Dr. Keith observes that the movement of the central tendon is decidedly more free than has hitherto been taught. A further observation as to the extent to which the heart is pulled downwards during the inspiratory descent of the muscle is contrary to the observations of others and certainly should be further investigated. The x rays show that the cardiac displacement as viewed from the front, in some individuals at least, is rather upwards than downwards, and possibly due to contraction of the abdominal muscles in forced expiration. Observations of the position and movements of the abdominal viscera in cases of indurative inflammation of the mediastinum should be of value in this connexion and might throw some light on the importance of the mediastinal supports of the diaphragm. Great importance is laid upon the effect of the abdominal muscles in replacing the abdominal viscera when these have been displaced by the contraction of the diaphragm, and the occurrence of enteroptosis is held to be in part a result of the failure of this action of replacement. Abdominal contraction, however, is probably not the only factor concerned for in the recumbent position at any rate the same replacement can be felt to occur during examination, when the abdominal muscles are certainly not in action to effect the reposition. An ingenious hypothesis is propounded by Dr. Keith to explain the comparative immunity of the left kidney from displacement, the easily displaced splenic flexure of the colon being supposed to act as a safety valve. Among other things which need to be explained are the occasional occurrence of enteroptosis in adult males without any constricting force having been applied or muscular paralysis being present, the occurrence of Riedel's lobe in infants without other abnormality, isolated displacements of the right kidney or another viscus, and those curious and localised temporary contractures of the large bowel which, by giving rise to sausage-shaped tumours in the regions of the cæcum, transverse colon, and iliac colon, mimic appendicular inflammation, intussusception, and malignant infiltrations.

We have indicated a few of the difficulties which still present themselves in attempting to understand the mechanism of these displacements. Dr. Keith's work has certainly added to our knowledge of the subject but the impression which remains is that the matter is not even yet satisfactorily cleared up. We have to record further work in parallel directions. We publish this week a note from Dr. C. T. Andrew, one of the demonstrators of anatomy in the University of Aberdeen, which deals with some interesting points allied to those raised by Dr. Keith in his Hunterian lectures. Dr. Andrew publishes the result of observations made with a view to ascertain the height of the diaphragm in the two sexes, the object of the inquiry being to find if any relation could be established between the height of the dome, the position of the viscera and the thickness of the abdominal wall. A sufficient number of examinations have not yet been made for any definite conclusions to be drawn, but from the study made in the dissecting room of nine consecutive bodies two male and seven female the frequency of many so-called abnormalities in the position of the viscera may be inferred.

Liquid Air and Typhoid Bacilli.

The paper communicated to the Royal Society on March 12th by Dr. Allan Macfadyen of the Jenner Institute marks a very decided advance in our knowledge of the cell-physiology of the bacillus typhi abdominalis whilst the full confirmation of the preliminary results obtained by the author promises a prophylactic and therapeutic agent in the treatment of typhoid fever which may replace the anti-typhoid "vaccines" and anti-typhoid sera at present in use. The typhoid bacillus is a member of that class of organisms which, although probably producing a powerful toxin as the result of its cell activity, has so far resisted all attempts to separate that toxin from the cell protoplasm of the bacillus itself. In other words, although the bacillus produce a toxin whilst actively multiplying within the body tissues—which toxin is undoubtedly responsible for many of the clinical manifestations of enteric fever—this toxin is insoluble in the ordinary nutrient media employed in the artificial cultivation of the bacillus under laboratory conditions. Hence such 'anti' sera as have been elaborated are bactericidal or anti-bacterial and not actively antitoxic. For some years past Dr. Macfadyen has been experimenting with various members of the class of bacteria which form these intracellular or so-called "insoluble" toxins, attempting at first to obtain the cell juices by trituration of the bacteria with fine silver sand and subsequent expression by means of a hydraulic press. In all these operations, however, an appreciable amount of heat is evolved, thereby inducing chemical changes in the juice obtained and introducing numerous fallacies in the interpretation of the results of the experiments.
